Informatica Big Data Management
(Version 10.1)

User Guide

This Informatica product (the "Software") includes certain drivers (the "DataDirect Drivers") from DataDirect Technologies, an operating company of Progress Software Corporation ("DataDirect") which are subject to the following terms and conditions:

1. THE DATADIRECT DRIVERS ARE PROVIDED "AS IS" WITHOUT WARRANTY OF ANY KIND, EITHER EXPRESSED OR IMPLIED, INCLUDING BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE AND NON-INFRINGEMENT.
2. IN NO EVENT WILL DATADIRECT OR ITS THIRD PARTY SUPPLIERS BE LIABLE TO THE END-USER CUSTOMER FOR ANY DIRECT, INDIRECT, INCIDENTAL, SPECIAL, CONSEQUENTIAL OR OTHER DAMAGES ARISING OUT OF THE USE OF THE ODBC DRIVERS, WHETHER OR NOT INFORMED OF THE POSSIBILITIES OF DAMAGES IN ADVANCE. THESE LIMITATIONS APPLY TO ALL CAUSES OF ACTION, INCLUDING, WITHOUT LIMITATION, BREACH OF CONTRACT, BREACH OF WARRANTY, NEGLIGENCE, STRICT LIABILITY, MISREPRESENTATION AND OTHER TORTS.

Preface

The *Informatica Big Data Management User Guide* provides information about how to configure Informatica products for Hadoop.

Informatica Resources

**Informatica Network**

Informatica Network hosts Informatica Global Customer Support, the Informatica Knowledge Base, and other product resources. To access Informatica Network, visit [https://network.informatica.com](https://network.informatica.com).

As a member, you can:

- Access all of your Informatica resources in one place.
- Search the Knowledge Base for product resources, including documentation, FAQs, and best practices.
- View product availability information.
- Review your support cases.
- Find your local Informatica User Group Network and collaborate with your peers.

**Informatica Knowledge Base**

Use the Informatica Knowledge Base to search Informatica Network for product resources such as documentation, how-to articles, best practices, and PAMs.

To access the Knowledge Base, visit [https://kb.informatica.com](https://kb.informatica.com). If you have questions, comments, or ideas about the Knowledge Base, contact the Informatica Knowledge Base team at KB_Feedback@informatica.com.

**Informatica Documentation**

If you have questions, comments, or ideas about this documentation, contact the Informatica Documentation team through email at infa_documentation@informatica.com.
Informatica Product Availability Matrixes

Product Availability Matrixes (PAMs) indicate the versions of operating systems, databases, and other types of data sources and targets that a product release supports. If you are an Informatica Network member, you can access PAMs at https://network.informatica.com/community/informatica-network/product-availability-matrices.

Informatica Velocity

Informatica Velocity is a collection of tips and best practices developed by Informatica Professional Services. Developed from the real-world experience of hundreds of data management projects, Informatica Velocity represents the collective knowledge of our consultants who have worked with organizations from around the world to plan, develop, deploy, and maintain successful data management solutions.

If you are an Informatica Network member, you can access Informatica Velocity resources at http://velocity.informatica.com.

If you have questions, comments, or ideas about Informatica Velocity, contact Informatica Professional Services at ips@informatica.com.

Informatica Marketplace

The Informatica Marketplace is a forum where you can find solutions that augment, extend, or enhance your Informatica implementations. By leveraging any of the hundreds of solutions from Informatica developers and partners, you can improve your productivity and speed up time to implementation on your projects. You can access Informatica Marketplace at https://marketplace.informatica.com.

Informatica Global Customer Support

You can contact a Global Support Center by telephone or through Online Support on Informatica Network.

To find your local Informatica Global Customer Support telephone number, visit the Informatica website at the following link: http://www.informatica.com/us/services-and-training/support-services/global-support-centers.

If you are an Informatica Network member, you can use Online Support at http://network.informatica.com.
This chapter includes the following topics:

- **Informatica Big Data Management Overview**, 10
- **Big Data Management Tasks**, 11
- **Big Data Management Component Architecture**, 14
- **Big Data Management Engines**, 16
- **Big Data Process**, 19

**Informatica Big Data Management Overview**

Informatica Big Data Management enables your organization to process large, diverse, and fast changing data sets so you can get insights into your data. Use Big Data Management to perform big data integration and transformation without writing or maintaining Apache Hadoop code.

Use Big Data Management to collect diverse data faster, build business logic in a visual environment, and eliminate hand-coding to get insights on your data. Consider implementing a big data project in the following situations:

- The volume of the data that you want to process is greater than 10 terabytes.
- You need to analyze or capture data changes in microseconds.
- The data sources are varied and range from unstructured text to social media data.

You can identify big data sources and perform profiling to determine the quality of the data. You can build the business logic for the data and push this logic to the Hadoop cluster for faster and more efficient processing. You can view the status of the big data processing jobs and view how the big data queries are performing.

You can use multiple product tools and clients such as Informatica Developer (the Developer tool) and Informatica Administrator (the Administrator tool) to access big data functionality. Big Data Management connects to third-party applications such as the Hadoop Distributed File System (HDFS) and NoSQL databases such as HBase on a Hadoop cluster on different Hadoop distributions.

The Developer tool includes the native and Hadoop run-time environments for optimal processing. Use the native run-time environment to process data that is less than 10 terabytes. In the native environment, the Data Integration Service processes the data. The Hadoop run-time environment can optimize mapping performance and process data that is greater than 10 terabytes. In the Hadoop environment, the Data Integration Service pushes the processing to nodes in a Hadoop cluster.
When you run a mapping in the Hadoop environment, you can select to use the Spark engine, the Blaze engine, or the Hive engine to run the mapping.

**Example**

You are an investment banker who needs to calculate the popularity and risk of stocks and then match stocks to each customer based on the preferences of the customer. Your CIO wants to automate the process of calculating the popularity and risk of each stock, match stocks to each customer, and then send an email with a list of stock recommendations for all customers.

You consider the following requirements for your project:

- The volume of data generated by each stock is greater than 10 terabytes.
- You need to analyze the changes to the stock in microseconds.
- The stock is included in Twitter feeds and company stock trade websites, so you need to analyze these social media sources.

Based on your requirements, you work with the IT department to create mappings to determine the popularity of a stock. One mapping tracks the number of times the stock is included in Twitter feeds, and another mapping tracks the number of times customers inquire about the stock on the company stock trade website.

**Big Data Management Tasks**

Use Big Data Management when you want to access, analyze, prepare, transform, and stream data faster than traditional data processing environments.

You can use Big Data Management for the following tasks:

- Read from and write to diverse big data sources and targets.
- Perform data replication on a Hadoop cluster.
- Perform data discovery.
- Perform data lineage on big data sources.
- Stream machine data.
- Manage big data relationships.

**Note:** The *Informatica Big Data Management User Guide* describes how to run big data mappings in the native environment or the Hadoop environment. For information on specific license and configuration requirements for a task, refer to the related product guides.

**Read from and Write to Big Data Sources and Targets**

In addition to relational and flat file data, you can access unstructured and semi-structured data, social media data, and data in a Hive or Hadoop Distributed File System (HDFS) environment.

You can access the following types of data:

**Transaction data**

You can access different types of transaction data, including data from relational database management systems, online transaction processing systems, online analytical processing systems, enterprise resource planning systems, customer relationship management systems, mainframe, and cloud.
Unstructured and semi-structured data

You can use parser transformations to read and transform unstructured and semi-structured data. For example, you can use the Data Processor transformation in a workflow to parse a Microsoft Word file to load customer and order data into relational database tables.

You can use HParser to transform complex data into flattened, usable formats for Hive, PIG, and MapReduce processing. HParser processes complex files, such as messaging formats, HTML pages and PDF documents. HParser also transforms formats such as ACORD, HIPAA, HL7, EDI-X12, EDIFACT, AFP, and SWIFT.

For more information, see the Data Transformation HParser Operator Guide.

Social media data

You can use PowerExchange adapters for social media to read data from social media web sites like Facebook, Twitter, and LinkedIn. You can also use the PowerExchange for DataSift to extract real-time data from different social media web sites and capture data from DataSift regarding sentiment and language analysis. You can use PowerExchange for Web Content-Kapow to extract data from any web site.

For more information about PowerExchange adapters for social media, see the related PowerExchange adapter guides.

Data in Hive and HDFS

You can use other PowerExchange adapters to read data from or write data to Hadoop. For example, you can use PowerExchange for Hive to read data from or write data to Hive. Also, you can use PowerExchange for HDFS to extract data from and load data to HDFS.

For more information about PowerExchange adapters, see the related PowerExchange adapter guides.

Perform Data Discovery

Data discovery is the process of discovering the metadata of source systems that include content, structure, patterns, and data domains. Content refers to data values, frequencies, and data types. Structure includes candidate keys, primary keys, foreign keys, and functional dependencies. The data discovery process offers advanced profiling capabilities.

In the native environment, you can define a profile to analyze data in a single data object or across multiple data objects. In the Hadoop environment, you can push column profiles and the data domain discovery process to the Hadoop cluster.

Run a profile to evaluate the data structure and to verify that data columns contain the types of information you expect. You can drill down on data rows in profiled data. If the profile results reveal problems in the data, you can apply rules to fix the result set. You can create scorecards to track and measure data quality before and after you apply the rules. If the external source metadata of a profile or scorecard changes, you can synchronize the changes with its data object. You can add comments to profiles so that you can track the profiling process effectively.

For more information, see the Informatica Data Discovery Guide.

Perform Data Lineage on Big Data Sources

Perform data lineage analysis in Enterprise Information Catalog for big data sources and targets.

Use Live Data Map to create a Cloudera Navigator resource to extract metadata for big data sources and targets and perform data lineage analysis on the metadata. Cloudera Navigator is a data management tool.
for the Hadoop platform that enables users to track data access for entities and manage metadata about the entities in a Hadoop cluster.

You can create one Cloudera Navigator resource for each Hadoop cluster that is managed by Cloudera Manager. Live Data Map extracts metadata about entities from the cluster based on the entity type.

Live Data Map extracts metadata for the following entity types:

- HDFS files and directories
- Hive tables, query templates, and executions
- Oozie job templates and executions
- Pig tables, scripts, and script executions
- YARN job templates and executions

**Note**: Live Data Map does not extract metadata for MapReduce job templates or executions.

For more information, see the *Live Data Map Administrator Guide*.

### Stream Machine Data

You can stream machine data in real time. To stream machine data, use Informatica Vibe Data Stream for Machine Data (Vibe Data Stream).

Vibe Data Stream is a highly available, distributed, real-time application that collects and aggregates machine data. You can collect machine data from different types of sources and write to different types of targets. Vibe Data Stream consists of source services that collect data from sources and target services that aggregate and write data to a target.

For more information, see the *Informatica Vibe Data Stream for Machine Data User Guide*.

### Manage Big Data Relationships

You can manage big data relationships by integrating data from different sources and indexing and linking the data in a Hadoop environment. Use Big Data Management to integrate data from different sources. Then use the MDM Big Data Relationship Manager to index and link the data in a Hadoop environment.

MDM Big Data Relationship Manager indexes and links the data based on the indexing and matching rules. You can configure rules based on which to link the input records. MDM Big Data Relationship Manager uses the rules to match the input records and then group all the matched records. MDM Big Data Relationship Manager links all the matched records and creates a cluster for each group of the matched records. You can load the indexed and matched record into a repository.

For more information, see the *MDM Big Data Relationship Management User Guide*.
Big Data Management Component Architecture

The Big Data Management components include client tools, application services, repositories, and third-party tools that Big Data Management uses for a big data project. The specific components involved depend on the task you perform.

The following image shows the components of Big Data Management:

Clients and Tools

Based on your product license, you can use multiple Informatica tools and clients to manage big data projects.

Use the following tools to manage big data projects:

Informatica Administrator

Monitor the status of profile, mapping, and MDM Big Data Relationship Management jobs on the Monitoring tab of the Administrator tool. The Monitoring tab of the Administrator tool is called the Monitoring tool. You can also design a Vibe Data Stream workflow in the Administrator tool.

Informatica Analyst

Create and run profiles on big data sources, and create mapping specifications to collaborate on projects and define business logic that populates a big data target with data.
Informatica Developer

Create and run profiles against big data sources, and run mappings and workflows on the Hadoop cluster from the Developer tool.

Application Services

Big Data Management uses application services in the Informatica domain to process data.

Big Data Management uses the following application services:

**Analyst Service**

The Analyst Service runs the Analyst tool in the Informatica domain. The Analyst Service manages the connections between service components and the users that have access to the Analyst tool.

**Data Integration Service**

The Data Integration Service can process mappings in the native environment or push the mapping for processing to the Hadoop cluster in the Hadoop environment. The Data Integration Service also retrieves metadata from the Model repository when you run a Developer tool mapping or workflow. The Analyst tool and Developer tool connect to the Data Integration Service to run profile jobs and store profile results in the profiling warehouse.

**Model Repository Service**

The Model Repository Service manages the Model repository. The Model Repository Service connects to the Model repository when you run a mapping, mapping specification, profile, or workflow.

Repositories

Big Data Management uses repositories and other databases to store data related to connections, source metadata, data domains, data profiling, data masking, and data lineage. Big Data Management uses application services in the Informatica domain to access data in repositories.

Big Data Management includes the following databases:

**Model repository**

The Model repository stores profiles, data domains, mapping, and workflows that you manage in the Developer tool. The Model repository also stores profiles, data domains, and mapping specifications that you manage in the Analyst tool.

**Profiling warehouse**

The Data Integration Service runs profiles and stores profile results in the profiling warehouse.

**Reference Data Warehouse**

A relational database that stores data values for the reference table objects that you define in the Model repository. When you add data to a reference table, the Content Management Service writes the data values to a table in the reference data warehouse.

Hadoop Environment

Big Data Management connects to Hadoop clusters that are distributed by third-parties. Hadoop is an open-source software framework that enables distributed processing of large data sets across clusters of machines. You might also need to use third-party software clients to set up and manage your Hadoop cluster.

Big Data Management can connect to Hadoop as a data source and push job processing to the Hadoop cluster. It can also connect to HDFS, which enables high performance access to files across the cluster.
can connect to Hive, which is a data warehouse that connects to HDFS and uses SQL-like queries to run MapReduce jobs on Hadoop, or YARN, which can manage Hadoop clusters more efficiently. It can also connect to NoSQL databases such as HBase, which is a database comprising key-value pairs on Hadoop that performs operations in real-time.

The Data Integration Service pushes mapping and profiling jobs to the Blaze, Spark, or Hive engine in the Hadoop environment.

**Hadoop Utilities**

Big Data Management uses third-party Hadoop utilities such as Sqoop to process data efficiently.

Sqoop is a Hadoop command line program to process data between relational databases and HDFS through MapReduce programs. You can use Sqoop to import and export data. When you use Sqoop, you do not need to install the relational database client and software on any node in the Hadoop cluster.

To use Sqoop, you must configure Sqoop properties in a JDBC connection and run the mapping in the Hadoop environment. You can configure Sqoop connectivity for relational data objects, customized data objects, and logical data objects that are based on a JDBC-compliant database. For example, you can configure Sqoop connectivity for the following databases:

- Aurora
- Greenplum
- IBM DB2
- IBM DB2 for z/OS
- Microsoft SQL Server
- Netezza
- Oracle
- Teradata

The Model Repository Service uses JDBC to import metadata. The Data Integration Service runs the mapping in the Hadoop run-time environment and pushes the job processing to Sqoop. The Sqoop program then creates MapReduce jobs in the Hadoop cluster, which perform the import and export job in parallel.

**Big Data Management Engines**

When you run a mapping in the Hadoop environment, you can choose the environment to run the mapping in, native environment or Hadoop environment. If you run the mapping in the Hadoop environment, the mapping will run on the Blaze engine, the Spark engine, or the Hive engine.

When you validate a mapping, you can validate it against one or all of the engines. The Developer tool returns validation messages for each engine. You can then choose to run the mapping in the native environment or in a Hadoop environment or in the native environment. When you run the mapping in the native environment, the Data Integration Service processes the mapping logic. When you run the mapping in the Hadoop environment, the Data Integration Service determines the best engine to run the mapping. The Data Integration Service translates the mapping logic into code that the engine can process, and it transfers the code to the engine.
Blaze Engine Architecture

To run a mapping on the Informatica Blaze engine, the Data Integration Service submits jobs to the Blaze engine executor. The Blaze engine executor is a software component that enables communication between the Data Integration Service and the Blaze engine components on the Hadoop cluster.

The following Blaze engine components appear on the Hadoop cluster:

- Grid Manager. Manages tasks for batch processing.
- Orchestrator. Schedules and processes parallel data processing tasks on a cluster.
- DTM Process Manager. Manages the DTM Processes.
- DTM Processes. An operating system process started to run DTM instances.
- Data Exchange Framework. Shuffles data between different processes that process the data on cluster nodes.

The following image shows how a Hadoop cluster processes jobs sent from the Blaze engine executor:

The following events occur when the Data Integration Service submits jobs to the Blaze engine executor:

1. The Blaze engine executor receives a job request from the LDTM.
2. It initializes the communication with the Grid Manager to initialize Blaze engine components on the Hadoop cluster, and it queries the Grid Manager for an available Orchestrator.
3. The Orchestrator communicates with the Grid Manager and the Resource Manager for available resources on the Hadoop cluster.
4. The Resource Manager sends a job request to the Node Manager on the Hadoop cluster.
5. The Node Manager sends the tasks to the DTM Processes through the DTM Process Manager.
6. The DTM Processes communicate with the Data Exchange Framework to send and receive data across processing units that run on the cluster nodes.
Spark Engine Architecture

The Data Integration Service can use the Spark engine on a Hadoop cluster to run Model repository mappings.

To run a mapping on the Spark engine, the Data Integration Service sends a mapping application to the Spark executor. The Spark executor submits the job to the Hadoop cluster to run.

The following image shows how a Hadoop cluster processes jobs sent from the Spark executor:

The following events occur when Data Integration Service runs a mapping on the Spark engine:

1. The Logical Data Translation Manager translates the mapping into a Scala program, packages it as an application, and sends it to the Spark executor.
2. The Spark executor submits the application to the Resource Manager in the Hadoop cluster and requests resources to run the application.
3. The Resource Manager identifies the Node Managers that can provide resources, and it assigns jobs to the data nodes.
4. Driver and Executor processes are launched in data nodes where the Spark application runs.

Hive Engine Architecture

The Data Integration Service can use the Hive engine to run Model repository mappings or profiles on a Hadoop cluster.

To run a mapping or profile with the Hive engine, the Data Integration Service creates HiveQL queries based on the transformation or profiling logic. The Data Integration Service submits the HiveQL queries to the Hive driver. The Hive driver converts the HiveQL queries to MapReduce jobs, and then sends the jobs to the Hadoop cluster.
The following diagram shows the architecture of how a Hadoop cluster processes MapReduce jobs sent from the Hive driver:

The following events occur when the Hive driver sends jobs to the Hadoop cluster:

1. The Hive driver sends the MapReduce jobs to the Resource Manager in the Hadoop cluster.
2. The Resource Manager sends the jobs request to the Node Manager that retrieves a list of data nodes that can process the MapReduce jobs.
3. The Node Manager assigns MapReduce jobs to the data nodes.
4. The Hive driver also connects to the Hive metadata database through the Hive metastore to determine where to create temporary tables. The Hive driver uses temporary tables to process the data. The Hive driver removes temporary tables after completing the task.

Big Data Process

As part of a big data project, you collect the data from diverse data sources. You can perform profiling, cleansing, and matching for the data. You build the business logic for the data and push the transformed data to the data warehouse. Then you can perform business intelligence on a view of the data.

Based on your big data project requirements, you can perform the following high-level tasks:

1. Collect the data.
2. Cleanse the data.
3. Transform the data.
4. Process the data.
5. Monitor jobs.
Step 1. Collect the Data

Identify the data sources from which you need to collect the data.

Big Data Management provides several ways to access your data in and out of Hadoop based on the data types, data volumes, and data latencies in the data.

You can use PowerExchange adapters to connect to multiple big data sources. You can schedule batch loads to move data from multiple source systems to HDFS without the need to stage the data. You can move changed data from relational and mainframe systems into HDFS or the Hive warehouse. For real-time data feeds, you can move data off message queues and into HDFS.

You can collect the following types of data:
- Transactional
- Interactive
- Log file
- Sensor device
- Document and file
- Industry format

Step 2. Cleanse the Data

Cleanse the data by profiling, cleaning, and matching your data. You can view data lineage for the data.

You can perform data profiling to view missing values and descriptive statistics to identify outliers and anomalies in your data. You can view value and pattern frequencies to isolate inconsistencies or unexpected patterns in your data. You can drill down on the inconsistent data to view results across the entire data set.

You can automate the discovery of data domains and relationships between them. You can discover sensitive data such as social security numbers and credit card numbers so that you can mask the data for compliance.

After you are satisfied with the quality of your data, you can also create a business glossary from your data. You can use the Analyst tool or Developer tool to perform data profiling tasks. Use the Analyst tool to perform data discovery tasks. Use Metadata Manager to perform data lineage tasks.

Step 3. Transform the Data

You can build the business logic to parse data in the Developer tool. Eliminate the need for hand-coding the transformation logic by using pre-built Informatica transformations to transform data.

Step 4. Process the Data

Based on your business logic, you can determine the optimal run-time environment to process your data. If your data is less than 10 terabytes, consider processing your data in the native environment. If your data is greater than 10 terabytes, consider processing your data in the Hadoop environment.

Step 5. Monitor Jobs

Monitor the status of your processing jobs. You can view monitoring statistics for your processing jobs in the Monitoring tool. After your processing jobs complete you can get business intelligence and analytics from your data.
Connections

This chapter includes the following topics:

- Connections, 21
- Hadoop Connection Properties, 22
- HDFS Connection Properties, 30
- HBase Connection Properties, 31
- Hive Connection Properties, 32
- JDBC Connection Properties, 38
- Creating a Connection to Access Sources or Targets, 43
- Creating a Hadoop Connection, 44

Connections

Define the connections that you want to use to access data in HBase, HDFS, Hive, or relational databases, or run a mapping on a Hadoop cluster. You can create the connections using the Developer tool, Administrator tool, and infacmd.

You can create the following types of connections:

**Hadoop connection**

Create a Hadoop connection to run mappings on the Hadoop cluster. Select the Hadoop connection if you select the Hadoop run-time environment. You must also select the Hadoop connection to validate a mapping to run on the Hadoop cluster. Before you run mappings in the Hadoop cluster, review the information in this guide about rules and guidelines for mappings that you can run in the Hadoop cluster.

**HDFS connection**

Create an HDFS connection to read data from or write data to the HDFS file system on the Hadoop cluster.

**HBase connection**

Create an HBase connection to access HBase. The HBase connection is a NoSQL connection.

**Hive connection**

Create a Hive connection to access Hive as a source or target. You can access Hive as a source if the mapping is enabled for the native or Hadoop environment. You can access Hive as a target only if the mapping uses the Hive engine.
JDBC connection

Create a JDBC connection and configure Sqoop properties in the connection to import and export relational data through Sqoop. You must also create a Hadoop connection to run the mapping on the Hadoop cluster.

Note: For information about creating connections to other sources or targets such as social media web sites or Teradata, see the respective PowerExchange adapter user guide for information.

Hadoop Connection Properties

Use the Hadoop connection to configure mappings to run on a Hadoop cluster. A Hadoop connection is a cluster type connection. You can create and manage a Hadoop connection in the Administrator tool or the Developer tool. You can use infacmd to create a Hadoop connection. Hadoop connection properties are case sensitive unless otherwise noted.

The following image shows the Hadoop connection properties:
**General Properties**

The following table describes the general connection properties for the Hadoop connection:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>The name of the connection. The name is not case sensitive and must be unique within the domain. You can change this property after you create the connection. The name cannot exceed 128 characters, contain spaces, or contain the following special characters: ~ ` ! $ % ^ &amp; * ( ) - + = [ ]</td>
</tr>
<tr>
<td>ID</td>
<td>String that the Data Integration Service uses to identify the connection. The ID is not case sensitive. It must be 255 characters or less and must be unique in the domain. You cannot change this property after you create the connection. Default value is the connection name.</td>
</tr>
<tr>
<td>Description</td>
<td>The description of the connection. Enter a string that you can use to identify the connection. The description cannot exceed 4,000 characters.</td>
</tr>
<tr>
<td>Location</td>
<td>The domain where you want to create the connection. Select the domain name.</td>
</tr>
<tr>
<td>Type</td>
<td>The connection type. Select Hadoop.</td>
</tr>
</tbody>
</table>
Common Attributes - Hadoop Cluster Properties

The following table describes the connection properties that you configure for the Hadoop cluster:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
</table>
| **Resource Manager Address**     | The service within Hadoop that submits requests for resources or spawns YARN applications. Use the following format:  
  `<hostname><port>`  
  **Where**  
  - `<hostname>` is the host name or IP address of the Yarn resource manager.  
  - `<port>` is the port on which the Yarn resource manager listens for remote procedure calls (RPC).  
  **For example, enter:**  
  `myhostame:8032`  
  You can also get the Resource Manager Address property from yarn-site.xml located in the following directory on the Hadoop cluster: `/etc/hadoop/conf/`  
  The Resource Manager Address appears as the following property in yarn-site.xml:  
  `<property>`  
  `<name>yarn.resourcemanager.address</name>`  
  `<value>hostname:port</value>`  
  `<description>The address of the applications manager interface in the Resource Manager.</description>`  
  `</property>`  
  **Optionally, if the `yarn.resourcemanager.address` property is not configured in yarn-site.xml, you can find the host name from the `yarn.resourcemanager.hostname` or `yarn.resourcemanager.scheduler.address` properties in yarn-site.xml. You can then configure the Resource Manager Address in the Hadoop connection with the following value: `hostname:8032`** |
| **Default File System URI**      | The URI to access the default Hadoop Distributed File System. Use the following connection URI:  
  `hdfs://<node name><port>`  
  **Where**  
  - `<node name>` is the host name or IP address of the NameNode.  
  - `<port>` is the port on which the NameNode listens for remote procedure calls (RPC).  
  **For example, enter:**  
  `hdfs://myhostame:8020/`  
  You can also get the Default File System URI property from core-site.xml located in the following directory on the Hadoop cluster: `/etc/hadoop/conf/`  
  Use the value from the `fs.defaultFS` property found in core-site.xml.  
  **For example, use the following value:**  
  `<property>`  
  `<name>fs.defaultFS</name>`  
  `<value>hdfs://localhost:8020</value>`  
  `</property>`  
  **If the Hadoop cluster runs MapR, use the following URI to access the MapR File system:**  
  `maprfs://.` |
**Common Attributes - Common Properties**

The following table describes the common connection properties that you configure for the Hadoop connection:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Impersonation User Name</td>
<td>User name of the user that the Data Integration Service impersonates to run mappings on a Hadoop cluster. If the Hadoop cluster uses Kerberos authentication, the principal name for the JDBC connection string and the user name must be the same. Note: You must use user impersonation for the Hadoop connection if the Hadoop cluster uses Kerberos authentication. If the Hadoop cluster does not use Kerberos authentication, the user name depends on the behavior of the JDBC driver. If you do not specify a user name, the Hadoop cluster authenticates jobs based on the operating system profile user name of the machine that runs the Data Integration Service.</td>
</tr>
<tr>
<td>Temporary Table Compression Codec</td>
<td>Hadoop compression library for a compression codec class name.</td>
</tr>
<tr>
<td>Codec Class Name</td>
<td>Codec class name that enables data compression and improves performance on temporary staging tables.</td>
</tr>
<tr>
<td>Hadoop Connection Custom Properties</td>
<td>Custom properties that are unique to the Hadoop connection. You can specify multiple properties. Use the following format: (&lt;\text{property1}&gt;=\text{value}&gt;) Where - &lt;property1&gt; is a Blaze, Hive, or Hadoop property. - \text{value} is the value of the Hive or Hadoop property. To specify multiple properties use &amp; as the property separator. Use custom properties only at the request of Informatica Global Customer Support.</td>
</tr>
</tbody>
</table>
Hive Pushdown - Hive Pushdown Configuration

The following table describes the connection properties that you configure to push mapping logic to the Hadoop cluster:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
</table>
| Environment SQL                 | SQL commands to set the Hadoop environment. The Data Integration Service executes the environment SQL at the beginning of each Hive script generated in a Hive execution plan. The following rules and guidelines apply to the usage of environment SQL:  
  - Use the environment SQL to specify Hive queries.  
  - Use the environment SQL to set the classpath for Hive user-defined functions and then use environment SQL or PreSQL to specify the Hive user-defined functions. You cannot use PreSQL in the data object properties to specify the classpath. The path must be the fully qualified path to the JAR files used for user-defined functions. Set the parameter hive.aux.jars.path with all the entries in infapdo.aux.jars.path and the path to the JAR files for user-defined functions.  
  - You can use environment SQL to define Hadoop or Hive parameters that you want to use in the PreSQL commands or in custom queries.  
  - If you use multiple values for the environment SQL, ensure that there is no space between the values.  
  The following sample text shows two values that can be used for the Environment SQL property:  
    set hive.execution.engine='tez';set hive.exec.dynamic.partition.mode='nonstrict'; |
| Database Name                   | Namespace for tables. Use the name `default` for tables that do not have a specified database name. |
| Hive Warehouse Directory on HDFS| The absolute HDFS file path of the default database for the warehouse that is local to the cluster. For example, the following file path specifies a local warehouse: `/user/hive/warehouse`  
  For Cloudera CDH, if the Metastore Execution Mode is remote, then the file path must match the file path specified by the Hive Metastore Service on the Hadoop cluster.  
  You can get the value for the Hive Warehouse Directory on HDFS from the hive.metastore.warehouse.dir property in hive-site.xml located in the following directory on the Hadoop cluster: `/etc/hadoop/conf/`  
  For example, use the following value:  
    `<property><name>hive.metastore.warehouse.dir</name><value>/user/hive/warehouse</value><description>location of the warehouse directory</description></property>`  
  For MapR, hive-site.xml is located in the following directory: `/opt/mapr/hive/hive versions>/conf`. |

Hive Pushdown - Hive Configuration

You can use the values for Hive configuration properties from hive-site.xml or mapred-site.xml located in the following directory on the Hadoop cluster: `/etc/hadoop/conf/`. 
The following table describes the connection properties that you configure for the Hive engine:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Metastore Execution Mode</td>
<td>Controls whether to connect to a remote metastore or a local metastore. By default, local is selected. For a local metastore, you must specify the Metastore Database URI, Metastore Database Driver, Username, and Password. For a remote metastore, you must specify only the Remote Metastore URI. You can get the value for the Metastore Execution Mode from hive-site.xml. The Metastore Execution Mode appears as the following property in hive-site.xml:&lt;p&gt;&lt;property&gt;&lt;name&gt;hive.metastore.local&lt;/name&gt;&lt;value&gt;true&lt;/value&gt;&lt;/property&gt;&lt;/p&gt; &lt;p&gt;Note: The hive.metastore.local property is deprecated in hive-site.xml for Hive server versions 0.9 and above. If the hive.metastore.local property does not exist but the hive.metastore.uris property exists, and you know that the Hive server has started, you can set the connection to a remote metastore.&lt;/p&gt;</td>
</tr>
<tr>
<td>Metastore Database URI</td>
<td>The JDBC connection URI used to access the data store in a local metastore setup. Use the following connection URI: &lt;p&gt;jdbc:&lt;datastore type&gt;://&lt;node name&gt;:&lt;port&gt;&lt;/database name&gt;&lt;/p&gt; where - &lt;node name&gt; is the host name or IP address of the data store. - &lt;data store type&gt; is the type of the data store. - &lt;port&gt; is the port on which the data store listens for remote procedure calls (RPC). - &lt;database name&gt; is the name of the database. For example, the following URI specifies a local metastore that uses MySQL as a data store: &lt;p&gt;jdbc:mysql://hostname23:3306/metastore&lt;/p&gt; You can get the value for the Metastore Database URI from hive-site.xml. The Metastore Database URI appears as the following property in hive-site.xml:&lt;p&gt;&lt;property&gt;&lt;name&gt;javax.jdo.option.ConnectionURL&lt;/name&gt;&lt;value&gt;jdbc:mysql://MYHOST/metastore&lt;/value&gt;&lt;/property&gt;&lt;/p&gt;</td>
</tr>
<tr>
<td>Metastore Database Driver</td>
<td>Driver class name for the JDBC data store. For example, the following class name specifies a MySQL driver: &lt;p&gt;com.mysql.jdbc.Driver&lt;/p&gt; You can get the value for the Metastore Database Driver from hive-site.xml. The Metastore Database Driver appears as the following property in hive-site.xml:&lt;p&gt;&lt;property&gt;&lt;name&gt;javax.jdo.option.ConnectionDriverName&lt;/name&gt;&lt;value&gt;com.mysql.jdbc.Driver&lt;/value&gt;&lt;/property&gt;&lt;/p&gt;</td>
</tr>
<tr>
<td>Metastore Database User Name</td>
<td>The metastore database user name. You can get the value for the Metastore Database User Name from hive-site.xml. The Metastore Database User Name appears as the following property in hive-site.xml:&lt;p&gt;&lt;property&gt;&lt;name&gt;javax.jdo.option.ConnectionUserName&lt;/name&gt;&lt;value&gt;hiveuser&lt;/value&gt;&lt;/property&gt;&lt;/p&gt;</td>
</tr>
<tr>
<td>Property</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
</tbody>
</table>
| Metastore Database Password   | The password for the metastore user name. You can get the value for the Metastore Database Password from hive-site.xml. The Metastore Database Password appears as the following property in hive-site.xml:  
<property>
  <name>javax.jdo.option.ConnectionPassword</name>
  <value>password</value>
</property>                                                                                      |
| Remote Metastore URI          | The metastore URI used to access metadata in a remote metastore setup. For a remote metastore, you must specify the Thrift server details.  
Use the following connection URI:  
thrift://<hostname>:<port>  
Where  
- `<hostname>` is name or IP address of the Thrift metastore server.  
- `<port>` is the port on which the Thrift server is listening.  
For example, enter: thrift://myhostname:9083/  
You can get the value for the Remote Metastore URI from hive-site.xml. The Remote Metastore URI appears as the following property in hive-site.xml:  
<property>
  <name>hive.metastore.uris</name>
  <value>thrift://<n.n.n.n>:9083</value>
  <description>IP address or fully-qualified domain name and port of the metastore host</description>
</property> |
The following table describes the connection properties that you configure for the Blaze engine:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Engine Type</strong></td>
<td>The engine that the Hadoop environment uses to run a mapping on the Hadoop cluster. Select a value from the drop down list.</td>
</tr>
<tr>
<td></td>
<td>For example select: MRv2</td>
</tr>
<tr>
<td></td>
<td>To set the engine type in the Hadoop connection, you must get the value for the mapreduce.framework.name property from mapred-site.xml located in the following directory on the Hadoop cluster: /etc/hadoop/conf/</td>
</tr>
<tr>
<td></td>
<td>If the value for mapreduce.framework.name is classic, select mrv1 as the engine type in the Hadoop connection.</td>
</tr>
<tr>
<td></td>
<td>If the value for mapreduce.framework.name is yarn, you can select the mrv2 or tez as the engine type in the Hadoop connection. Do not select Tez if Tez is not configured for the Hadoop cluster.</td>
</tr>
<tr>
<td></td>
<td>You can also set the value for the engine type in hive-site.xml. The engine type appears as the following property in hive-site.xml:</td>
</tr>
<tr>
<td></td>
<td>&lt;property&gt;                                                                            &lt;name&gt;hive.execution.engine&lt;/name&gt;</td>
</tr>
<tr>
<td></td>
<td>&lt;value&gt;tez&lt;/value&gt;                                                                     &lt;description&gt;Chooses execution engine. Options are: mr (MapReduce, default) or tez (Hadoop 2 only)&lt;/description&gt;</td>
</tr>
<tr>
<td></td>
<td>&lt;/property&gt;</td>
</tr>
<tr>
<td><strong>Job Monitoring URL</strong></td>
<td>The URL for the MapReduce JobHistory server. You can use the URL for the JobTracker URI if you use MapReduce version 1.</td>
</tr>
<tr>
<td></td>
<td>Use the following format:                                                              &lt;hostname&gt;:&lt;port&gt;</td>
</tr>
<tr>
<td></td>
<td>Where                                                                                  - &lt;hostname&gt; is the host name or IP address of the JobHistory server.</td>
</tr>
<tr>
<td></td>
<td>- &lt;port&gt; is the port on which the JobHistory server listens for remote procedure calls (RPC).</td>
</tr>
<tr>
<td></td>
<td>For example, enter: myhostname:8021</td>
</tr>
<tr>
<td></td>
<td>You can get the value for the Job Monitoring URL from mapred-site.xml. The Job Monitoring URL appears as the following property in mapred-site.xml:</td>
</tr>
<tr>
<td></td>
<td>&lt;property&gt;                                                                            &lt;name&gt;mapred.job.tracker&lt;/name&gt;</td>
</tr>
<tr>
<td></td>
<td>&lt;value&gt;myhostname:8021&lt;/value&gt;                                                         &lt;description&gt;The host and port that the MapReduce job tracker runs at.&lt;/description&gt;</td>
</tr>
<tr>
<td></td>
<td>&lt;/property&gt;</td>
</tr>
</tbody>
</table>

**Blaze Engine**

The following table describes the connection properties that you configure for the Blaze engine:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Temporary Working Directory on HDFS</strong></td>
<td>The HDFS file path of the directory that the Blaze engine uses to store temporary files. Verify that the directory exists. The YARN user, Blaze engine user, and mapping impersonation user must have write permission on this directory.</td>
</tr>
<tr>
<td></td>
<td>For example, enter: /blaze/workdir</td>
</tr>
<tr>
<td><strong>Blaze Service User Name</strong></td>
<td>The operating system profile user name for the Blaze engine.</td>
</tr>
<tr>
<td><strong>Minimum Port</strong></td>
<td>The minimum value for the port number range for the Blaze engine.</td>
</tr>
<tr>
<td></td>
<td>For example, enter: 12300</td>
</tr>
<tr>
<td>Property</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Maximum Port</td>
<td>The maximum value for the port number range for the Blaze engine. For example, enter: 12600</td>
</tr>
<tr>
<td>Yarn Queue Name</td>
<td>The YARN scheduler queue name used by the Blaze engine that specifies available resources on a cluster. The name is case sensitive.</td>
</tr>
<tr>
<td>Blaze Service Custom Properties</td>
<td>Custom properties that are unique to the Blaze engine. You can specify multiple properties. Use the following format:</td>
</tr>
<tr>
<td></td>
<td><code>&lt;property1&gt;=&lt;value&gt;</code></td>
</tr>
<tr>
<td></td>
<td>Where</td>
</tr>
<tr>
<td></td>
<td>- <code>&lt;property1&gt;</code> is a Blaze engine optimization property.</td>
</tr>
<tr>
<td></td>
<td>- <code>&lt;value&gt;</code> is the value of the Blaze engine optimization property.</td>
</tr>
<tr>
<td></td>
<td>To enter multiple properties, separate each name-value pair with the following text: <code>&amp;:</code>.</td>
</tr>
<tr>
<td></td>
<td>Use custom properties only at the request of Informatica Global Customer Support.</td>
</tr>
</tbody>
</table>

**Spark Engine**

The following table describes the connection properties that you configure for the Spark engine:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Spark HDFS Staging Directory</td>
<td>The HDFS file path of the directory that the Spark engine uses to store temporary files for running jobs. The YARN user, Spark engine user, and mapping impersonation user must have write permission on this directory.</td>
</tr>
<tr>
<td>Spark Execution Parameters</td>
<td>An optional list of configuration parameters to apply to the Spark engine. You can change the default Spark configuration properties values, such as <code>spark.executor.memory</code> or <code>spark.driver.cores</code>. Use the following format: <code>&lt;property1&gt;=&lt;value&gt;</code></td>
</tr>
<tr>
<td></td>
<td>- <code>&lt;property1&gt;</code> is a Spark configuration property.</td>
</tr>
<tr>
<td></td>
<td>- <code>&lt;value&gt;</code> is the value of the property.</td>
</tr>
<tr>
<td></td>
<td>For example, you can configure a YARN scheduler queue name that specifies available resources on a cluster: <code>spark.yarn.queue=TestQ</code></td>
</tr>
<tr>
<td></td>
<td>To enter multiple properties, separate each name-value pair with the following text: <code>&amp;:</code>.</td>
</tr>
</tbody>
</table>

**HDFS Connection Properties**

Use a Hadoop File System (HDFS) connection to access data in the Hadoop cluster. The HDFS connection is a file system type connection. You can create and manage an HDFS connection in the Administrator tool, Analyst tool, or the Developer tool. HDFS connection properties are case sensitive unless otherwise noted.

**Note:** The order of the connection properties might vary depending on the tool where you view them.
The following table describes HDFS connection properties:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>Name of the connection. The name is not case sensitive and must be unique within the domain. The name cannot exceed 128 characters, contain spaces, or contain the following special characters: `~ ! $ % ^ &amp; * ( ) - + = [ ]</td>
</tr>
<tr>
<td>ID</td>
<td>String that the Data Integration Service uses to identify the connection. The ID is not case sensitive. It must be 255 characters or less and must be unique in the domain. You cannot change this property after you create the connection. Default value is the connection name.</td>
</tr>
<tr>
<td>Description</td>
<td>The description of the connection. The description cannot exceed 765 characters.</td>
</tr>
<tr>
<td>Location</td>
<td>The domain where you want to create the connection. Not valid for the Analyst tool.</td>
</tr>
<tr>
<td>Type</td>
<td>The connection type. Default is Hadoop File System.</td>
</tr>
<tr>
<td>User Name</td>
<td>User name to access HDFS.</td>
</tr>
<tr>
<td>NameNode URI</td>
<td>The URI to access HDFS. Use the following format to specify the NameNode URI in Cloudera and Hortonworks distributions: hdfs://&lt;namenode&gt;:&lt;port&gt; Where - <code>&lt;namenode&gt;</code> is the host name or IP address of the NameNode. - <code>&lt;port&gt;</code> is the port that the NameNode listens for remote procedure calls (RPC). Use one of the following formats to specify the NameNode URI in MapR distribution: - maprfs:// - maprfs://mapr/my.cluster.com/ Where <code>my.cluster.com</code> is the cluster name that you specify in the <code>mapr-clusters.conf</code> file.</td>
</tr>
</tbody>
</table>

**HBase Connection Properties**

Use an HBase connection to access HBase. The HBase connection is a NoSQL connection. You can create and manage an HBase connection in the Administrator tool or the Developer tool. Hbase connection properties are case sensitive unless otherwise noted.

The following table describes HBase connection properties:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>The name of the connection. The name is not case sensitive and must be unique within the domain. You can change this property after you create the connection. The name cannot exceed 128 characters, contain spaces, or contain the following special characters: `~ ! $ % ^ &amp; * ( ) - + = [ ]</td>
</tr>
<tr>
<td>ID</td>
<td>String that the Data Integration Service uses to identify the connection. The ID is not case sensitive. It must be 255 characters or less and must be unique in the domain. You cannot change this property after you create the connection. Default value is the connection name.</td>
</tr>
<tr>
<td>Property</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Description</td>
<td>The description of the connection. The description cannot exceed 4,000 characters.</td>
</tr>
<tr>
<td>Location</td>
<td>The domain where you want to create the connection.</td>
</tr>
<tr>
<td>Type</td>
<td>The connection type. Select HBase.</td>
</tr>
<tr>
<td>ZooKeeper Host(s)</td>
<td>Name of the machine that hosts the ZooKeeper server. The name is case sensitive. When the ZooKeeper runs in the replicated mode, specify a comma-separated list of servers in the ZooKeeper quorum servers. If the TCP connection to the server breaks, the client connects to a different server in the quorum.</td>
</tr>
<tr>
<td>ZooKeeper Port</td>
<td>Port number of the machine that hosts the ZooKeeper server.</td>
</tr>
<tr>
<td>Enable Kerberos Connection</td>
<td>Enables the Informatica domain to communicate with the HBase master server or region server that uses Kerberos authentication.</td>
</tr>
<tr>
<td>HBase Master Principal</td>
<td>Service Principal Name (SPN) of the HBase master server. Enables the ZooKeeper server to communicate with an HBase master server that uses Kerberos authentication. Enter a string in the following format: hbase/&lt;domain.name&gt;@&lt;YOUR-REALM&gt; Where: - domain.name is the domain name of the machine that hosts the HBase master server. - YOUR-REALM is the Kerberos realm.</td>
</tr>
<tr>
<td>HBase Region Server Principal</td>
<td>Service Principal Name (SPN) of the HBase region server. Enables the ZooKeeper server to communicate with an HBase region server that uses Kerberos authentication. Enter a string in the following format: hbase_rs/&lt;domain.name&gt;@&lt;YOUR-REALM&gt; Where: - domain.name is the domain name of the machine that hosts the HBase master server. - YOUR-REALM is the Kerberos realm.</td>
</tr>
</tbody>
</table>

**Hive Connection Properties**

Use the Hive connection to access Hive data. A Hive connection is a database type connection. You can create and manage a Hive connection in the Administrator tool, Analyst tool, or the Developer tool. Hive connection properties are case sensitive unless otherwise noted.

**Note:** The order of the connection properties might vary depending on the tool where you view them.
The following table describes Hive connection properties:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Name</td>
<td>The name of the connection. The name is not case sensitive and must be unique within the domain. You can change this property after you create the connection. The name cannot exceed 128 characters, contain spaces, or contain the following special characters: ~ ` ! $ % ^ &amp; * ( ) _ + = { } [ ]</td>
</tr>
<tr>
<td>ID</td>
<td>String that the Data Integration Service uses to identify the connection. The ID is not case sensitive. It must be 255 characters or less and must be unique in the domain. You cannot change this property after you create the connection. Default value is the connection name.</td>
</tr>
<tr>
<td>Description</td>
<td>The description of the connection. The description cannot exceed 4000 characters.</td>
</tr>
<tr>
<td>Location</td>
<td>The domain where you want to create the connection. Not valid for the Analyst tool.</td>
</tr>
<tr>
<td>Type</td>
<td>The connection type. Select Hive.</td>
</tr>
</tbody>
</table>
| Connection Modes | Hive connection mode. Select at least one of the following options:  
- Access HiveServer2 to run mappings. Select this option if you want to use Hive as a source or a target. You can enable the same connection or another Hive connection to run mappings in HiveServer2 in the Hadoop cluster.  
- Access Hive CLI to run mappings. Select this option if you want to use the Hive CLI to run mappings in the Hadoop cluster.  
You can select both the options. If you select both the options, the connection created can be used for Hive as a source or target or to run the mapping in the Pushdown mode. |
<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>User Name</td>
<td>User name of the user that the Data Integration Service impersonates to run mappings on a Hadoop cluster. The user name depends on the JDBC connection string that you specify in the Metadata Connection String or Data Access Connection String for the native environment. If the Hadoop cluster runs Hortonworks HDP, you must provide a user name. If you use Tez to run mappings, you must provide the user account for the Data Integration Service. If you do not use Tez to run mappings, you can use an impersonation user account. If the Hadoop cluster uses Kerberos authentication, the principal name for the JDBC connection string and the user name must be the same. Otherwise, the user name depends on the behavior of the JDBC driver. With Hive JDBC driver, you can specify a user name in many ways and the user name can become a part of the JDBC URL. If the Hadoop cluster does not use Kerberos authentication, the user name depends on the behavior of the JDBC driver. If you do not specify a user name, the Hadoop cluster authenticates jobs based on the following criteria: - The Hadoop cluster does not use Kerberos authentication. It authenticates jobs based on the operating system profile user name of the machine that runs the Data Integration Service. - The Hadoop cluster uses Kerberos authentication. It authenticates jobs based on the SPN of the Data Integration Service.</td>
</tr>
</tbody>
</table>
## Properties to Access Hive as Source or Target

The following table describes the connection properties that you configure to access Hive as a source or target:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
</table>
| Metadata Connection String| The JDBC connection URI used to access the metadata from the Hadoop server. You can use PowerExchange for Hive to communicate with a HiveServer service or HiveServer2 service. To connect to HiveServer, specify the connection string in the following format: `jdbc: hive2://<hostname>[:<port>]/<db>` Where  
- `<hostname>` is name or IP address of the machine on which HiveServer2 runs.  
- `<port>` is the port number on which HiveServer2 listens.  
- `<db>` is the database name to which you want to connect. If you do not provide the database name, the Data Integration Service uses the default database details.  
To connect to HiveServer 2, use the connection string format that Apache Hive implements for that specific Hadoop Distribution. For more information about Apache Hive connection string formats, see the Apache Hive documentation. |
| Bypass Hive JDBC Server    | JDBC driver mode. Select the check box to use the embedded JDBC driver mode. To use the JDBC embedded mode, perform the following tasks:  
- Verify that Hive client and Informatica services are installed on the same machine.  
- Configure the Hive connection properties to run mappings in the Hadoop cluster. If you choose the non-embedded mode, you must configure the Data Access Connection String. Informatica recommends that you use the JDBC embedded mode. |
| Data Access Connection String | The connection string to access data from the Hadoop data store. To connect to HiveServer, specify the non-embedded JDBC mode connection string in the following format: `jdbc: hive2://<hostname>[:<port>]/<db>` Where  
- `<hostname>` is name or IP address of the machine on which HiveServer2 runs.  
- `<port>` is the port number on which HiveServer2 listens.  
- `<db>` is the database to which you want to connect. If you do not provide the database name, the Data Integration Service uses the default database details.  
To connect to HiveServer 2, use the connection string format that Apache Hive implements for the specific Hadoop Distribution. For more information about Apache Hive connection string formats, see the Apache Hive documentation. |
## Properties to Run Mappings in Hadoop Cluster

The following table describes the Hive connection properties that you configure when you want to use the Hive connection to run Informatica mappings in the Hadoop cluster:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database Name</td>
<td>Namespace for tables. Use the name <code>default</code> for tables that do not have a specified database name.</td>
</tr>
<tr>
<td>Default FS URI</td>
<td>The URI to access the default Hadoop Distributed File System. Use the following connection URI: hdfs://&lt;node name&gt;;&lt;port&gt; Where</td>
</tr>
<tr>
<td></td>
<td>- <code>&lt;node name&gt;</code> is the host name or IP address of the NameNode.</td>
</tr>
</tbody>
</table>
|                                   | - `<port>` is the port on which the NameNode listens for remote procedure calls (RPC). If the Hadoop cluster runs MapR, use the following URI to access the MapR File system: maprfs:///.
| JobTracker/Yarn Resource Manager URI | The service within Hadoop that submits the MapReduce tasks to specific nodes in the cluster. Use the following format:  |
|                                   | `<hostname>` is the host name or IP address of the JobTracker or Yarn resource manager.                                                     |
|                                   | `<port>` is the port on which the JobTracker or Yarn resource manager listens for remote procedure calls (RPC). If the cluster uses MapR with YARN, use the value specified in the yarn.resourcemanager.address property in yarn-site.xml. You can find yarn-site.xml in the following directory on the NameNode of the cluster: /opt/mapr/hadoop/hadoop-2.5.1/etc/hadoop. MapR with MapReduce 1 supports a highly available JobTracker. If you are using MapR distribution, define the JobTracker URI in the following format maprfs:///|
| Hive Warehouse Directory on HDFS  | The absolute HDFS file path of the default database for the warehouse that is local to the cluster. For example, the following file path specifies a local warehouse:  |
|                                   | `/user/hive/warehouse` For Cloudera CDH, if the Metastore Execution Mode is remote, then the file path must match the file path specified by the Hive Metastore Service on the Hadoop cluster. For MapR, use the value specified for the hive.metastore.warehouse.dir property in hive-site.xml. You can find hive-site.xml in the following directory on the node that runs HiveServer2: /opt/mapr/hive/hive-0.13/conf. |
### Advanced Hive/Hadoop Properties

Configures or overrides Hive or Hadoop cluster properties in hive-site.xml on the machine on which the Data Integration Service runs. You can specify multiple properties. Select **Edit** to specify the name and value for the property. The property appears in the following format:

\[
\text{<property1>=<value>}
\]

Where
- `<property1>` is a Hive or Hadoop property in hive-site.xml.
- `<value>` is the value of the Hive or Hadoop property.

When you specify multiple properties, `&` appears as the property separator.

The maximum length for the format is 1 MB.

If you enter a required property for a Hive connection, it overrides the property that you configure in the Advanced Hive/Hadoop Properties.

The Data Integration Service adds or sets these properties for each map-reduce job. You can verify these properties in the JobConf of each mapper and reducer job. Access the JobConf of each job from the Jobtracker URL under each map-reduce job.

The Data Integration Service writes messages for these properties to the Data Integration Service logs. The Data Integration Service must have the log tracing level set to log each row or have the log tracing level set to verbose initialization tracing.

For example, specify the following properties to control and limit the number of reducers to run a mapping job:

```
mapred.reduce.tasks=2&hive.exec.reducers.max=10
```

### Temporary Table Compression Codec

Hadoop compression library for a compression codec class name.

### Codec Class Name

Codec class name that enables data compression and improves performance on temporary staging tables.

### Metastore Execution Mode

Controls whether to connect to a remote metastore or a local metastore. By default, local is selected. For a local metastore, you must specify the Metastore Database URI, Driver, Username, and Password. For a remote metastore, you must specify only the Remote Metastore URI.

### Metastore Database URI

The JDBC connection URI used to access the data store in a local metastore setup. Use the following connection URI:

```
jdbc:<datastore type>:<node name>:<port>/<database name>
```

where
- `<node name>` is the host name or IP address of the data store.
- `<data store type>` is the type of the data store.
- `<port>` is the port on which the data store listens for remote procedure calls (RPC).
- `<database name>` is the name of the database.

For example, the following URI specifies a local metastore that uses MySQL as a data store:

```
jdbc:mysql://hostname23:3306/metastore
```

For MapR, use the value specified for the **javax.jdo.option.ConnectionURL** property in hive-site.xml. You can find hive-site.xml in the following directory on the node where HiveServer 2 runs: `/opt/mapr/hive/hive-0.13/conf`. 
You can use a JDBC connection to access tables in a database. You can create and manage a JDBC connection in the Administrator tool, the Developer tool, or the Analyst tool.

**Note:** The order of the connection properties might vary depending on the tool where you view them.

The following table describes JDBC connection properties:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Metastore Database Driver</td>
<td>Driver class name for the JDBC data store. For example, the following class name specifies a MySQL driver: com.mysql.jdbc.Driver. For MapR, use the value specified for the javax.jdo.option.ConnectionDriverName property in hive-site.xml. You can find hive-site.xml in the following directory on the node where HiveServer 2 runs: /opt/mapr/hive/hive-0.13/conf.</td>
</tr>
<tr>
<td>Metastore Database Username</td>
<td>The metastore database user name. For MapR, use the value specified for the javax.jdo.option.ConnectionUserName property in hive-site.xml. You can find hive-site.xml in the following directory on the node where HiveServer 2 runs: /opt/mapr/hive/hive-0.13/conf.</td>
</tr>
<tr>
<td>Metastore Database Password</td>
<td>The password for the metastore user name. For MapR, use the value specified for the javax.jdo.option.ConnectionPassword property in hive-site.xml. You can find hive-site.xml in the following directory on the node where HiveServer 2 runs: /opt/mapr/hive/hive-0.13/conf.</td>
</tr>
<tr>
<td>Remote Metastore URI</td>
<td>The metastore URI used to access metadata in a remote metastore setup. For a remote metastore, you must specify the Thrift server details. Use the following connection URI: thrift://&lt;hostname&gt;:&lt;port&gt; Where: - &lt;hostname&gt; is name or IP address of the Thrift metastore server. - &lt;port&gt; is the port on which the Thrift server is listening. For MapR, use the value specified for the hive.metastore.uris property in hive-site.xml. You can find hive-site.xml in the following directory on the node where HiveServer 2 runs: /opt/mapr/hive/hive-0.13/conf.</td>
</tr>
</tbody>
</table>

**JDBC Connection Properties**

You can use a JDBC connection to access tables in a database. You can create and manage a JDBC connection in the Administrator tool, the Developer tool, or the Analyst tool.

**Note:** The order of the connection properties might vary depending on the tool where you view them.

The following table describes JDBC connection properties:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database Type</td>
<td>The database type.</td>
</tr>
</tbody>
</table>
| Name     | Name of the connection. The name is not case sensitive and must be unique within the domain. The name cannot exceed 128 characters, contain spaces, or contain the following special characters: `~ ` ! $ @ & * ( ) + = { [ ] } | \ : ; " ' < , > . ? /`
<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID</td>
<td>String that the Data Integration Service uses to identify the connection. The ID is not case sensitive. It must be 255 characters or less and must be unique in the domain. You cannot change this property after you create the connection. Default value is the connection name.</td>
</tr>
<tr>
<td>Description</td>
<td>The description of the connection. The description cannot exceed 765 characters.</td>
</tr>
<tr>
<td>User Name</td>
<td>The database user name.</td>
</tr>
<tr>
<td>Password</td>
<td>The password for the database user name.</td>
</tr>
<tr>
<td>JDBC Driver Class Name</td>
<td>Name of the JDBC driver class. The following list provides the driver class name that you can enter for the applicable database type:</td>
</tr>
<tr>
<td></td>
<td>- DataDirect JDBC driver class name for Oracle: com.informatica.jdbc.oracle.OracleDriver</td>
</tr>
<tr>
<td></td>
<td>- DataDirect JDBC driver class name for IBM DB2: com.informatica.jdbc.db2.DB2Driver</td>
</tr>
<tr>
<td></td>
<td>- DataDirect JDBC driver class name for Microsoft SQL Server: com.informatica.jdbc.sqlserver.SQLServerDriver</td>
</tr>
<tr>
<td></td>
<td>- DataDirect JDBC driver class name for Sybase ASE: com.informatica.jdbc.sybase.SybaseDriver</td>
</tr>
<tr>
<td></td>
<td>- DataDirect JDBC driver class name for Informix: com.informatica.jdbc.informix.InformixDriver</td>
</tr>
<tr>
<td></td>
<td>- DataDirect JDBC driver class name for MySQL: com.informatica.jdbc.mysql.MySQLDriver</td>
</tr>
<tr>
<td></td>
<td>For more information about which driver class to use with specific databases, see the vendor documentation.</td>
</tr>
<tr>
<td>Connection String</td>
<td>Connection string to connect to the database. Use the following connection string: jdbc:&lt;subprotocol&gt;:&lt;subname&gt;</td>
</tr>
<tr>
<td>Environment SQL</td>
<td>Optional. Enter SQL commands to set the database environment when you connect to the database. The Data Integration Service executes the connection environment SQL each time it connects to the database.</td>
</tr>
<tr>
<td>Transaction SQL</td>
<td>Optional. Enter SQL commands to set the database environment when you connect to the database. The Data Integration Service executes the transaction environment SQL at the beginning of each transaction.</td>
</tr>
<tr>
<td>SQL Identifier Character</td>
<td>Type of character that the database uses to enclose delimited identifiers in SQL queries. The available characters depend on the database type.</td>
</tr>
<tr>
<td></td>
<td>Select (None) if the database uses regular identifiers. When the Data Integration Service generates SQL queries, the service does not place delimited characters around any identifiers.</td>
</tr>
<tr>
<td></td>
<td>Select a character if the database uses delimited identifiers. When the Data Integration Service generates SQL queries, the service encloses delimited identifiers within this character.</td>
</tr>
<tr>
<td>Support Mixed-case Identifiers</td>
<td>Enable if the database uses case-sensitive identifiers. When enabled, the Data Integration Service encloses all identifiers within the character selected for the SQL Identifier Character property.</td>
</tr>
<tr>
<td></td>
<td>When the SQL Identifier Character property is set to none, the Support Mixed-case Identifiers property is disabled.</td>
</tr>
<tr>
<td>Property</td>
<td>Description</td>
</tr>
<tr>
<td>----------------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>Pass-through security enabled</td>
<td>Enables pass-through security for the connection. When you enable pass-through security for a connection, the domain uses the client user name and password to log into the corresponding database, instead of the credentials defined in the connection object.</td>
</tr>
</tbody>
</table>
| Metadata Access Properties: Connection String| The JDBC connection URL that is used to access metadata from the database. The following list provides the connection string that you can enter for the applicable database type:
- DataDirect JDBC driver for Oracle: `jdbc:informatica:oracle://<hostname>:<port>;SID=<sid>`
- DataDirect JDBC driver for IBM DB2: `jdbc:informatica:db2://<hostname>:<port>;DatabaseName=<database name>`
- DataDirect JDBC driver for Microsoft SQL Server: `jdbc:informatica:sqlserver://<host>:<port>;DatabaseName=<database name>`
- DataDirect JDBC driver for Sybase ASE: `jdbc:informatica:sybase://<host>:<port>;DatabaseName=<database name>`
- DataDirect JDBC driver for Informix: `jdbc:informatica:informix://<host>:<port>;informixServer=<informix server name>;DatabaseName=<database name>`
- DataDirect JDBC driver for MySQL: `jdbc:informatica:mysql://<host>:<port>;DatabaseName=<database name>`

For more information about the connection string to use for specific databases, see the vendor documentation for the URL syntax.

| AdvancedJDBCSecurityOptions                  | Database parameters for metadata access to a secure database. Informatica treats the value of the AdvancedJDBCSecurityOptions field as sensitive data and stores the parameter string encrypted.

To connect to a secure database, include the following parameters:
- EncryptionMethod. Required. Indicates whether data is encrypted when transmitted over the network. This parameter must be set to SSL.
- ValidateServerCertificate. Optional. Indicates whether Informatica validates the certificate that is sent by the database server.
  - If this parameter is set to True, Informatica validates the certificate that is sent by the database server. If you specify the HostNameInCertificate parameter, Informatica also validates the host name in the certificate.
  - If this parameter is set to false, Informatica does not validate the certificate that is sent by the database server. Informatica ignores any truststore information that you specify.
- HostNameInCertificate. Optional. Host name of the machine that hosts the secure database. If you specify a host name, Informatica validates the host name included in the connection string against the host name in the SSL certificate.
- TrustStore. Required. Path and file name of the truststore file that contains the SSL certificate for the database.
- TrustStorePassword. Required. Password for the truststore file for the secure database. Not applicable for ODBC.

**Note:** Informatica appends the secure JDBC parameters to the connection string. If you include the secure JDBC parameters directly to the connection string, do not enter any parameters in the AdvancedJDBCSecurityOptions field.

<p>| Code Page                                    | The code page used to read from a source database or to write to a target database or file. |</p>
<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Environment SQL</td>
<td>SQL commands to set the database environment when you connect to the database. The Data Integration Service runs the connection environment SQL each time it connects to the database.</td>
</tr>
<tr>
<td>Transaction SQL</td>
<td>SQL commands to set the database environment when you connect to the database. The Data Integration Service runs the transaction environment SQL at the beginning of each transaction.</td>
</tr>
<tr>
<td>Retry Period</td>
<td>This property is reserved for future use.</td>
</tr>
<tr>
<td>SQL Identifier Character</td>
<td>The type of character used to identify special characters and reserved SQL keywords, such as WHERE. The Data Integration Service places the selected character around special characters and reserved SQL keywords. The Data Integration Service also uses this character for the Support Mixed-case Identifiers property. If you configure an SQL identifier character for a Sqoop source or target and the column name contains a comma, the Sqoop program ignores the SQL identifier character.</td>
</tr>
<tr>
<td>Support Mixed-case Identifiers</td>
<td>When enabled, the Data Integration Service places identifier characters around table, view, schema, synonym, and column names when generating and executing SQL against these objects in the connection. Use if the objects have mixed-case or lowercase names. By default, this option is not selected.</td>
</tr>
<tr>
<td>Use Sqoop Connector</td>
<td>Enables Sqoop connectivity for the data object that uses the JDBC connection. The Data Integration Service runs the mapping in the Hadoop run-time environment through Sqoop. You can configure Sqoop connectivity for relational data objects, customized data objects, and logical data objects that are based on a JDBC-compliant database. Select <strong>Sqoop v1.x</strong> to enable Sqoop connectivity. Default is <strong>None</strong>.</td>
</tr>
<tr>
<td>Sqoop Arguments</td>
<td>Enter the arguments that the Sqoop program must use to connect to the database. To enter multiple arguments, separate them with a space. If you do not enter Sqoop arguments, the Data Integration Service constructs the Sqoop command based on the JDBC connection properties.</td>
</tr>
</tbody>
</table>

**Sqoop Connection-Level Arguments**

In the JDBC connection, you can define the arguments that the Sqoop program must use to connect to the database. The Data Integration Service merges the arguments that you specify with the default command that it constructs based on the JDBC connection properties. The arguments that you specify take precedence over the JDBC connection properties.

If you want to use the same driver to import metadata and run the mapping, and do not want to specify any additional Sqoop arguments, select **Sqoop v1.x** from the **Use Sqoop Version** list and leave the **Sqoop Arguments** field empty in the JDBC connection. The Data Integration Service constructs the Sqoop command based on the JDBC connection properties that you specify.

However, if you want to use a different driver for run-time tasks or specify additional run-time Sqoop arguments, select **Sqoop v1.x** from the **Use Sqoop Version** list and specify the arguments in the **Sqoop Arguments** field.

You can configure the following Sqoop arguments in the JDBC connection:
driver

Defines the JDBC driver class that the Sqoop program must use to connect to the database.

Use the following syntax:

```
--driver <JDBC driver class>
```

For example, use the following syntax depending on the database type that you want to connect to:

- **Aurora**: `--driver com.mysql.jdbc.Driver`
- **Greenplum**: `--driver org.postgresql.Driver`
- **IBM DB2**: `--driver com.ibm.db2.jcc.DB2Driver`
- **IBM DB2 z/OS**: `--driver com.ibm.db2.jcc.DB2Driver`
- **Microsoft SQL Server**: `--driver com.microsoft.sqlserver.jdbc.SQLServerDriver`
- **Netezza**: `--driver org.netezza.Driver`
- **Oracle**: `--driver oracle.jdbc.driver.OracleDriver`
- **Teradata**: `--driver com.teradata.jdbc.TeraDriver`

connect

Defines the JDBC connection string that the Sqoop program must use to connect to the database. The JDBC connection string must be based on the driver that you define in the driver argument.

Use the following syntax:

```
--connect <JDBC connection string>
```

For example, use the following syntax depending on the database type that you want to connect to:

- **Aurora**: `--connect "jdbc:mysql://<host_name>:<port>/<schema_name>"
- **Greenplum**: `--connect jdbc:postgresql://<host_name>:<port>/<database_name>
- **IBM DB2**: `--connect jdbc:db2://<host_name>:<port>/<database_name>
- **IBM DB2 z/OS**: `--connect jdbc:db2://<host_name>:<port>/<database_name>
- **Microsoft SQL Server**: `--connect jdbc:sqlserver://<host_name>:<port or named_instance>;databaseName=<database_name>
- **Netezza**: `--connect "jdbc:netezza://<database_server_name>:<port>/
<database_name>;schema=<schema_name>"
- **Oracle**: `--connect jdbc:oracle:thin:@<database_host_name>:<database_port>:<database_SID>
- **Teradata**: `--connect jdbc:teradata://<host_name>/database=<database_name>

direct

When you read data from Oracle, you can configure the direct argument to enable the Sqoop program to use OraOop. OraOop is a specialized Sqoop plug-in for Oracle that uses native protocols to connect to the Oracle database. When the Sqoop program uses OraOop, the performance improves.

Use the following syntax:

```
--direct
```

When you use OraOop, you must use the following syntax to specify multiple arguments:

```
-D<argument=value> -D<argument=value>
```
Note: If you specify multiple arguments and include a space character between -D and the argument name-value pair, the Sqoop program considers only the first argument and ignores the remaining arguments.

If you do not configure the direct argument, the Sqoop program uses JDBC to import data.

For a complete list of the Sqoop arguments that you can configure, see the Sqoop documentation.

Creating a Connection to Access Sources or Targets

Create an HBase, HDFS, Hive, or JDBC connection before you import data objects, preview data, and profile data.

1. Click Window > Preferences.
2. Select Informatica > Connections.
3. Expand the domain in the Available Connections list.
4. Select the type of connection that you want to create:
   • To select an HBase connection, select NoSQL > HBase.
   • To select an HDFS connection, select File Systems > Hadoop File System.
   • To select a Hive connection, select Database > Hive.
   • To select a JDBC connection, select Database > JDBC.
5. Click Add.
6. Enter a connection name and optional description.
7. Click Next.
8. Configure the connection properties. For a Hive connection, you must choose the Hive connection mode and specify the commands for environment SQL. The SQL commands apply to both the connection modes. Select at least one of the following connection modes:

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Access HiveServer2 to run mappings</td>
<td>Use the connection to access Hive data. If you select this option and click Next, the Properties to Access Hive as a Source or Target page appears. Configure the connection strings. To run the mapping in HiveServer2 mode, click Next. The Properties used to Run Mappings in the Hadoop Cluster page appears. Configure the properties.</td>
</tr>
<tr>
<td>Access Hive CLI to run mappings.</td>
<td>Use the Hive connection to validate and run profiles in the Hadoop cluster. If you select this option and click Next, the Properties used to Run Mappings in the Hadoop Cluster page appears. Configure the properties.</td>
</tr>
</tbody>
</table>

9. Click Test Connection to verify the connection.

You can test a Hive connection that is configured to access Hive data. You cannot test a Hive connection that is configured to run Informatica mappings in the Hadoop cluster.

10. Click Finish.
Creating a Hadoop Connection

Create a Hadoop connection before you run a mapping in the Hadoop environment.

1. Click Window > Preferences.
2. Select Informatica > Connections.
3. Expand the domain in the Available Connections list.
4. Select the Cluster connection type in the Available Connections list and click Add.
   The New Cluster Connection dialog box appears.
5. Enter the general properties for the connection.

6. Click Next.
7. Enter the Hadoop cluster properties and the common properties for the Hadoop connection.
8. Click Next.
9. Enter the Hive pushdown configuration properties and the Hive configuration.
10. Click Next.
11. If you are using the Blaze engine, enter the properties for the Blaze engine.
12. If you are using the Spark engine, enter the properties for the Spark engine.
13. Click Finish.
Chapter 3

Mappings in a Hadoop Environment

This chapter includes the following topics:

- Mappings in a Hadoop Environment Overview, 45
- Mapping Run-time Properties, 46
- Data Warehouse Optimization Mapping Example, 48
- Sqoop Mappings in a Hadoop Environment, 50
- Rules and Guidelines for Mappings in a Hadoop Environment, 52
- Workflows that Run Mappings in a Hadoop Environment, 53
- Configuring a Mapping to Run in a Hadoop Environment, 53
- Mapping Execution Plans, 54
- Monitor Jobs, 58
- Hadoop Environment Logs, 61
- Optimization for the Hadoop Environment, 64
- Troubleshooting a Mapping in a Hadoop Environment, 67

Mappings in a Hadoop Environment Overview

Configure the Hadoop run-time environment in the Developer tool to optimize mapping performance and process data that is greater than 10 terabytes. In the Hadoop environment, the Data Integration Service pushes the processing to nodes on a Hadoop cluster. When you select the Hadoop environment, you can also select the engine to push the mapping logic to the Hadoop cluster.

You can run standalone mappings, mappings that are a part of a workflow in the Hadoop environment.

Based on the mapping logic, the Hadoop environment can use the following engines to push processing to nodes on a Hadoop cluster:

- Informatica Blaze engine. An Informatica proprietary engine for distributed processing on Hadoop.
- Spark engine. A high performance engine for batch processing that can run on a Hadoop cluster or on a Spark standalone mode cluster.
- Hive engine. A batch processing engine that uses Hadoop technology such as MapReduce or Tez.
You can select which engine the Data Integration Service uses. If you choose more than one engine, the Data Integration Service determines the engine to run the mapping during validation.

When you run a mapping in the Hadoop environment, you must configure a Hadoop connection for the mapping. When you edit the Hadoop connection, you can set the run-time properties for the Hadoop environment and the properties for the engine that runs the mapping.

You can view the execution plan for a mapping to run in the Hadoop environment. View the execution plan for the engine that the Data Integration Service selects to run the mapping.

You can monitor Hive queries and the Hadoop jobs in the Monitoring tool. Monitor the jobs on a Hadoop cluster with the YARN Web User Interface or the Blaze Job Monitor web application.

The Data Integration Service logs messages from the DTM, the Blaze engine, the Spark engine, and the Hive engine in the run-time log files.

## Mapping Run-time Properties

The mapping run-time properties depend on the environment that you select for the mapping.

The mapping properties contains the **Validation Environments** area and an **Execution Environment** area. The properties in the **Validation Environment** indicate whether the Developer tool validates the mapping definition for the native execution environment, the Hadoop execution environment, or both. When you run a mapping in the native environment, the Data Integration Service processes the mapping.

When you run a mapping in the Hadoop environment, the Data Integration Service pushes the mapping execution to the Hadoop cluster through a Hadoop connection. The Hadoop cluster processes the mapping.

The following image shows the mapping **Run-time** properties in a Hadoop environment:

![Mapping Run-time Properties](image)

### Validation Environments

The properties in the **Validation Environments** indicate whether the Developer tool validates the mapping definition for the native execution environment or the Hadoop execution environment.

You can configure the following properties for the **Validation Environments**:

- **Native**
  
  Default environment. The Data Integration Service runs the mapping in a native environment.

- **Hadoop**
  
  Run the mapping in the Hadoop environment. The Data Integration Service pushes the transformation logic to the Hadoop cluster through a Hive connection. The Hadoop cluster processes the data. Select
the Hive on MapReduce engine, the Blaze engine, or the Spark engine to process the mapping. The Hadoop connection must contain the configuration properties for each engine that you choose. If you choose Hive on MapReduce engine, you can also select the Hive version. Select a version number from the list or assign a parameter to the Hive version. The parameter must be a string that contains a version from the Hive version list. If you use the Blaze engine, you cannot clear the Hive on MapReduce engine.

You can use a mapping parameter to indicate the execution environment. When you select the execution environment, click **Assign Parameter**. Configure a string parameter. Set the default value to Native or Hive.

When you validate the mapping, validation occurs for each engine that you choose in the **Validation Environments**. The validation log might contain validation errors specific to each engine. If the mapping is valid for at least one mapping, the mapping is valid. The errors for the other engines appear in the validation log as warnings. If the mapping is valid for multiple Hadoop engines, you can view the execution plan to determine which engine will run the job. You can view the execution plan in the **Data Viewer** view.

The following image shows validation errors for the Blaze engine, the Spark engine, and the Hive on MapReduce engine:

![Validation Errors Image]

### Execution Environment

Configure Hadoop properties, Pushdown Configuration properties, and Source Configuration properties in the **Execution Environment** area.

Configure the following properties in a Hadoop Execution Environment:

<table>
<thead>
<tr>
<th>Name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Connection</td>
<td>Defines the connection information that the Data Integration Service requires to push the mapping execution to the Hadoop cluster. Select the Hadoop connection to run the mapping in the Hadoop cluster. You can assign a user-defined parameter for the Hadoop connection.</td>
</tr>
<tr>
<td>Execution Parameters</td>
<td>Overrides the Hadoop custom properties or the Spark default configuration parameters for the mapping. An execution parameter in the mapping properties overrides the same execution parameter that you enter in the Hadoop connection.</td>
</tr>
</tbody>
</table>
You can configure the following pushdown configuration properties:

<table>
<thead>
<tr>
<th>Name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pushdown type</td>
<td>Choose one of the following options:</td>
</tr>
<tr>
<td></td>
<td>- None. Select no pushdown type for the mapping.</td>
</tr>
<tr>
<td></td>
<td>- Source. The Data Integration Service tries to push down transformation logic to the source database.</td>
</tr>
<tr>
<td></td>
<td>- Full. The Data Integration pushes the full transformation logic to the source database.</td>
</tr>
<tr>
<td>Pushdown Capability</td>
<td>Optionally, if you choose full pushdown optimization and the mapping contains an Update Strategy transformation, you can choose a pushdown compatibility option or assign a pushdown compatibility parameter. Choose one of the following options:</td>
</tr>
<tr>
<td></td>
<td>- Multiple rows do not have the same key. The transformation connected to the Update Strategy transformation receives multiple rows without the same key. The Data Integration Service can push the transformation logic to the target.</td>
</tr>
<tr>
<td></td>
<td>- Multiple rows with the same key can be reordered. The target transformation connected to the Update Strategy transformation receives multiple rows with the same key that can be reordered. The Data Integration Service can push the Update Strategy transformation to the Hadoop environment.</td>
</tr>
<tr>
<td></td>
<td>- Multiple rows with the same key cannot be reordered. The target transformation connected to the Update Strategy transformation receives multiple rows with the same key that cannot be reordered. The Data Integration Service cannot push the Update Strategy transformation to the Hadoop environment.</td>
</tr>
</tbody>
</table>

You can configure the following source properties:

<table>
<thead>
<tr>
<th>Name</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Maximum Rows Read</td>
<td>Reserved for future use.</td>
</tr>
<tr>
<td>Maximum Runtime Interval</td>
<td>Reserved for future use.</td>
</tr>
<tr>
<td>State Store</td>
<td>Reserved for future use.</td>
</tr>
</tbody>
</table>

**Data Warehouse Optimization Mapping Example**

You can optimize an enterprise data warehouse with the Hadoop system to store more terabytes of data cheaply in the warehouse.

For example, you need to analyze customer portfolios by processing the records that have changed in a 24-hour time period. You can offload the data on Hadoop, find the customer records that have been inserted, deleted, and updated in the last 24 hours, and then update those records in your data warehouse. You can capture these changes even if the number of columns change or if the keys change in the source files.

To capture the changes, you can create the following mappings in the Developer tool:

**Mapping Day1**

Create a mapping to read customer data from flat files in a local file system and write to an HDFS target for the first 24-hour period.

**Mapping Day2**

Create a mapping to read customer data from flat files in a local file system and write to an HDFS target for the next 24-hour period.
Create a mapping to capture the changed data. The mapping reads data from HDFS and identifies the data that has changed. To increase performance, you configure the mapping to run on Hadoop cluster nodes in a Hadoop environment.

The following image shows the mapping `m_CDC_DWHOptimization`:

The mapping contains the following objects:

- **Read transformations.** Transformations that read data from HDFS files that were the targets of `Mapping_Day1` and `Mapping_Day2`. The Data Integration Service reads all of the data as a single column.
- **Expression transformations.** Extract a key from the non-key values in the data. The expressions use the `INSTR` function and `SUBSTR` function to perform the extraction of key values.
- **Joiner transformation.** Performs a full outer join on the two sources based on the keys generated by the Expression transformations.
- **Filter transformations.** Use the output of the Joiner transformation to filter rows based on whether or not the rows should be updated, deleted, or inserted.
- **Write transformations.** Transformations that write the data to three HDFS files based on whether the data is inserted, deleted, or updated.

Create a mapping to consolidate the data in the HDFS files and load the data to the data warehouse.
The following figure shows the mapping Consolidated_Mapping:

The mapping contains the following objects:

- Read transformations. Transformations that read data from HDFS files that were the target of the previous mapping are the sources of this mapping.
- Expression transformations. Add the deleted, updated, or inserted tags to the data rows.
- Union transformation. Combines the records.
- Write transformation. Transformation that writes data to the flat file that acts as a staging location on the local file system.

You can open each mapping and right-click to run the mapping. To run all mappings in sequence, use a workflow.

The following image shows the example Data Warehouse Optimization workflow:

To run the workflow, use the infacmd wfs startWorkflow command.

**Sqoop Mappings in a Hadoop Environment**

After you enable Sqoop in a JDBC connection and import a Sqoop source or target, you can create a mapping. You can then run the Sqoop mapping in the Hadoop run-time environment with a Hadoop connection. You can run Sqoop mappings on the Hive engine.

In the mapping, you can specify additional Sqoop arguments and disable the Sqoop connector.
Sqoop Mapping-Level Arguments

In the Sqoop mapping, you can define the arguments that the Sqoop program must use to process the data. The Data Integration Service merges the additional Sqoop arguments that you specify in the mapping with the arguments that you specified in the JDBC connection and constructs the Sqoop command.

The Sqoop arguments that you specify in the mapping take precedence over the arguments that you specified in the JDBC connection. However, if you do not enable the Sqoop connector in the JDBC connection but enable the Sqoop connector in the mapping, the Data Integration Service does not run the mapping through Sqoop. The Data Integration Service runs the mapping through JDBC.

You can configure the following Sqoop arguments in a Sqoop mapping:

num-mappers

Defines the number of map tasks that the Sqoop program must use to import and export data in parallel.

Use the following syntax:

```
--num-mappers <number of map tasks>
```

For example, to use 8 map tasks, configure the num-mappers argument as follows:

```
--num-mappers 8
```

If you configure the num-mappers argument, you must also configure the split-by argument to specify the column based on which the Sqoop program must split the work units. If you do not configure the split-by argument, the value of the num-mappers argument defaults to 1.

Use the num-mappers argument to increase the degree of parallelism. You might have to test different values for optimal performance.

split-by

Defines the column based on which the Sqoop program splits work units.

Use the following syntax:

```
--split-by <column name>
```

You can configure the split-by argument to improve the performance. If the primary key does not have an even distribution of values between the minimum and maximum range, you can configure the split-by argument to specify another column that has a balanced distribution of data to split the work units.

If you do not configure the split-by argument, the Sqoop program uses the primary key of the table to split the work units.

Consider the following restrictions when you configure the split-by argument:

- If you configure the split-by argument and the column based on which the work units will be split contains NULL values, the Sqoop program does not import the rows that contain NULL values. However, the mapping runs successfully and no error is written in the YARN log.
- If you configure the split-by argument and the column based on which the work units will be split contains special characters, the Sqoop import process fails.

batch

Indicates that the Sqoop program must export data in batches.

Use the following syntax:

```
--batch
```

You can configure the batch argument to improve the performance.

For a complete list of the Sqoop arguments that you can configure, see the Sqoop documentation.
Configuring Sqoop Properties in the Mapping

You can specify additional Sqoop arguments and disable the Sqoop connector at the mapping level. The Sqoop arguments that you specify at the mapping level take precedence over the arguments that you specified in the JDBC connection.

1. Open the mapping that contains the data object for which you want to configure Sqoop properties.
2. Select the Read or Write transformation that is associated with the data object.
3. Click the Advanced tab.
4. To disable the Sqoop connector for the data object, select the Disable Sqoop Connector check box.
5. Perform one of the following steps:
   - To specify additional Sqoop import arguments for the data object, enter the import arguments in the Additional Sqoop Import Arguments text box.
   - To specify additional Sqoop export arguments for the data object, enter the export arguments in the Additional Sqoop Export Arguments text box.

The Data Integration Service merges the additional Sqoop arguments that you specified in the mapping with the arguments that you specified in the JDBC connection and constructs the Sqoop command. The Data Integration Service then invokes the Sqoop program on a Hadoop node.

Rules and Guidelines for Mappings in a Hadoop Environment

You can run mappings in a Hadoop environment. When you run mappings in a Hadoop environment, some differences in processing and configuration apply.

The following processing differences apply to mappings in a Hadoop environment:

- A mapping is run in high precision mode in a Hadoop environment for Hive 0.11 and above.
- In a Hadoop environment, sources that have data errors in a column result in a null value for the column. In the native environment, the Data Integration Service does not process the rows that have data errors in a column.
- When you cancel a mapping that reads from a flat file source, the file copy process that copies flat file data to HDFS may continue to run. The Data Integration Service logs the command to kill this process in the Hive session log, and cleans up any data copied to HDFS. Optionally, you can run the command to kill the file copy process.
- When you set a limit on the number of rows read from the source for a Blaze mapping, the Data Integration Service runs the mapping with the Hive engine instead of the Blaze engine.

The following configuration differences apply to mappings in a Hadoop environment:

- Set the optimizer level to none or minimal if a mapping validates but fails to run. If you set the optimizer level to use cost-based or semi-join optimization methods, the Data Integration Service ignores this at runtime and uses the default.
- Mappings that contain a Hive source or a Hive target must use the same Hive connection to push the mapping to Hadoop.
The Data Integration Service ignores the data file block size configured for HDFS files in the hdfs-site.xml file. The Data Integration Service uses a default data file block size of 64 MB for HDFS files. To change the data file block size, copy 

```
/usr/lib/hadoop/conf/hdfs-site.xml
```
to the following location in the Hadoop distribution directory for the Data Integration Service node: 

```
/opt/Informatica/services/shared/hadoop/[Hadoop_distribution_name]/conf.
```
You can also update the data file block size in the following file: 

```
/opt/Informatica/services/shared/hadoop/[Hadoop_distribution_name]/conf/hive-default.xml.
```

### Workflows that Run Mappings in a Hadoop Environment

You can add a mapping that you configured to run in a Hadoop environment to a Mapping task in a workflow. When you deploy and run the workflow, the Mapping task runs the mapping.

You might decide to run a mapping from a workflow so that you can make decisions during the workflow run. You can configure a workflow to run multiple mappings in sequence or in parallel. You can configure a workflow to send emails that notify users about the status of the Mapping tasks.

When a Mapping task runs a mapping configured to run in a Hadoop environment, do not assign the Mapping task outputs to workflow variables. Mappings that run in a Hadoop environment do not provide the total number of target, source, and error rows. When a Mapping task includes a mapping that runs in a Hadoop environment, the task outputs contain a value of zero (0).

### Configuring a Mapping to Run in a Hadoop Environment

You can configure a mapping to run in a Hadoop environment. To configure a mapping, you must select the Hadoop validation environment and a Hadoop connection.

1. Select a mapping from a project or folder from the Object Explorer view to open in the editor.
2. In the Properties view, select the Run-time tab.
3. Select Hadoop as the value for the validation environment.

   The Hive on MapReduce, the Blaze, and the Spark engines are selected by default. To only use the Hive on MapReduce engine, clear the other engines. If you use the Blaze engine, you cannot clear the Hive on MapReduce engine.
4. In the execution environment, select Hadoop.

5. In the Hadoop environment, select Connection and use the drop down in the value field to browse for a connection or create a connection parameter:
   - To select a connection, click Browse and select a connection.
   - To create a connection parameter, click Assign Parameter.

6. Optionally, select Execution Parameters to override a Hadoop custom property or a Spark default configuration parameter.

7. Right-click an empty area in the editor and click Validate.
   The Developer tool validates the mapping.

8. View validation errors on the Validation Log tab.

9. Click the Data Viewer view.

10. Click Show Execution Plan to view the execution plan for the mapping.

Mapping Execution Plans

The Data Integration Service generates an execution plan to run mappings on a Blaze, Spark, or Hive engine. The Data Integration Service translates the mapping logic into code that the run-time engine can execute. You can view the plan in the Developer tool before you run the mapping and in the Administrator tool after you run the mapping.

The Data Integration Service generates mapping execution plans to run on the following engines:

Informatica Blaze engine

The Blaze engine execution plan simplifies the mapping into segments. It contains tasks to start the mapping, run the mapping, and clean up the temporary tables and files. It contains multiple tasklets and the task recovery strategy. It also contains pre- and post-grid task preparation commands for each mapping before running the main mapping on a Hadoop cluster. A pre-grid task can include a task such as copying data to HDFS. A post-grid task can include tasks such as cleaning up temporary files or copying data from HDFS.

Spark engine

The Spark execution plan shows the run-time Scala code that runs the mapping logic. A translation engine translates the mapping into an internal representation of the logic. The internal representation is rendered into Scala code that accesses the Spark API. You can view the Scala code in the execution plan to debug the logic.
**Hive engine**

The Hive execution plan is a series of Hive queries. The plan contains tasks to start the mapping, run the mapping, and clean up the temporary tables and files. You can view the Hive execution plan that the Data Integration Service generates before you run the mapping. When the Data Integration Service pushes the mapping to the Hive engine, it has a Hive executor that can process the mapping. The Hive executor simplifies the mapping to an equivalent mapping with a reduced set of instructions and generates a Hive execution plan.

**Blaze Engine Execution Plan Details**

You can view details of the Blaze engine execution plan in the Administrator tool and Developer tool.

In the Developer tool, the Blaze engine execution plan appears as a workflow. You can click on each component in the workflow to get the details.

The following image shows the Blaze execution plan in the Developer tool:

The Blaze engine execution plan workflow contains the following components:

- **Start task.** The workflow start task.
- **Command task.** The pre-processing or post-processing task for local data.
- **Grid mapping.** An Informatica mapping that the Blaze engine compiles and distributes across a cluster of nodes.
- **Grid task.** A parallel processing job request sent by the Blaze engine executor to the Grid Manager.
- **Grid segment.** Segment of a grid mapping that is contained in a grid task.
- **Tasklet.** A partition of a grid segment that runs on a separate DTM.

In the Administrator tool, the Blaze engine execution plan appears as a script.
The following image shows the Blaze execution script:

[Image of Blaze execution script]

In the Administrator tool, the Blaze engine execution plan has the following details:

- **Script ID.** Unique identifier for the Blaze engine script.
- **Script.** Blaze engine script that the Data Integration Service generates based on the mapping logic.
- **Depends on.** Tasks that the script depends on. Tasks include other scripts and Data Integration Service tasks, like the Start task.

### Spark Engine Execution Plan Details

You can view the details of a Spark engine execution plan from the Administrator tool or Developer tool.

The Spark engine execution plan shows the Scala code to run in the Hadoop cluster.

The following image shows the execution plan for a mapping to run on the Spark engine:

[Image of Spark execution plan]

The Spark engine execution plan has the following details:

- **Script ID.** Unique identifier for the Spark engine script.
- **Script.** Scala code that the Data Integration Service generates based on the mapping logic.
- **Depends on.** Tasks that the script depends on. Tasks include other scripts and Data Integration Service tasks.
Hive Engine Execution Plan Details

You can view the details of a Hive engine execution plan for a mapping from the Administrator tool or Developer tool.

The following table describes the properties of a Hive engine execution plan:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Script Name</td>
<td>Name of the Hive script.</td>
</tr>
<tr>
<td>Script</td>
<td>Hive script that the Data Integration Service generates based on the mapping logic.</td>
</tr>
<tr>
<td>Depends On</td>
<td>Tasks that the script depends on. Tasks include other scripts and Data Integration Service tasks, like the Start task.</td>
</tr>
</tbody>
</table>

Viewing the Execution Plan for a Mapping in the Developer Tool

You can view the Hive or Blaze engine execution plan for a mapping that runs in a Hadoop environment. You do not have to run the mapping to view the execution plan in the Developer tool.

**Note:** You can also view the execution plan in the Administrator tool.

1. To view the execution plan in the Developer tool, select the **Data Viewer** view for the mapping and click **Show Execution Plan**.
2. Select the **Data Viewer** view.
3. Select **Show Execution Plan**.
   The **Data Viewer** view shows the details for the execution plan.
Monitor Jobs

You can monitor statistics and view log events for a mapping job in the Monitoring tab of the Administrator tool. You can also monitor mapping jobs for the Blaze engine in the Blaze Job Monitor web application. Monitor mapping jobs for the Spark engine in the YARN web user interface.

The following image shows the Monitor tab in the Administrator tool:

The Monitor tab has the following views:

**Summary Statistics**

Use the Summary Statistics view to view graphical summaries of object states and distribution across the Data Integration Services. You can also view graphs of the memory and CPU that the Data Integration Services used to run the objects.

**Execution Statistics**

Use the Execution Statistics view to monitor properties, run-time statistics, and run-time reports. In the Navigator, you can expand a Data Integration Service to monitor Ad Hoc Jobs or expand an application to monitor deployed mapping jobs.

When you select Ad Hoc Jobs or deployed mapping jobs from an application in the Navigator of the Execution Statistics view, a list of jobs appears in the contents panel. The contents panel groups related jobs based on the job type. You can expand a job type to view the related jobs under it.

Access the following views the Execution Statistics view:

**Properties**

The Properties view shows the general properties about the selected job such as name, job type, user who started the job, and start time of the job. If you ran the mapping with the Blaze engine, you can also monitor jobs on the Hadoop cluster from the Monitoring URL that appears for the mapping in the general properties. The Monitoring URL opens the Blaze Job Monitor in a web page. The Blaze Job Monitor displays detailed monitoring statistics for a mapping such as the number of grid tasks, grid segments, or tasklets, and recovery attempts for each tasklet.
Blaze Execution Plan

The Blaze Execution Plan view appears when you view a mapping with the Blaze engine in the Hadoop environment and you click Blaze Execution Plan. The Blaze execution plan displays the Blaze engine script that the Data Integration Service generates based on the mapping logic. The execution plan includes the tasks that the script depends on. Each script has a unique identifier.

Spark Execution Plan

The Spark Execution Plan view appears when you view a mapping with the Spark engine in the Hadoop environment and you click Spark Execution Plan. When you view an execution plan for the mapping, the Data Integration Service translates the mapping to a Scala program and an optional set of commands. The execution plan shows the commands and the Scala program code.

Hive Execution Plan

The Hive Execution Plan view appears when you view a mapping with the Hive engine in the Hadoop environment and you click Hive Execution Plan. The Hive execution plan displays the Hive script that the Data Integration Service generates based on the mapping logic. The execution plan includes the Hive queries and Hive commands. Each script has a unique identifier.

Summary Statistics

The Summary Statistics view appears in the details panel when you select a mapping job in the contents panel. The Summary Statistics view displays throughput and resource usage statistics for the job run.

Note: Summary statistics are not available for a mapping that runs on the Spark engine.

Detailed Statistics

The Detailed Statistics view appears in the details panel when you select a mapping job in the contents panel. The Detailed Statistics view displays graphs of the throughput and resource usage statistics for the job run.

Note: Detailed statistics are not available for a mapping that runs on the Spark engine.

Accessing the Monitoring URL

The Monitoring URL opens the Blaze Job Monitor web application or the YARN web user interface. Access the Monitoring URL from the Execution Statistics view in the Administrator tool.

1. In the Monitor tab of the Administrator tool, click the Execution Statistics view.
2. Select Ad Hoc Jobs or select a deployed mapping job from an application in the Navigator.

The list of jobs appears in the contents panel.
3. Select a mapping job and expand the mapping to select a grid task for the mapping.

The Monitoring URL appears in the Properties view.

![Blaze Job Monitor](image)

### Monitor Blaze Engine Jobs

Use the Blaze Job Monitor application to monitor Blaze engine jobs on the Hadoop cluster. The Blaze engine monitoring URL appears in the Monitor tab of the Administrator tool when you view a Blaze engine mapping job. When you click the URL, the Blaze engine monitoring application opens in a web page.

The following image shows the Blaze Job Monitor:

![Blaze Job Monitor](image)
You can filter Blaze mapping jobs by the following task history:

- Grid task. A parallel processing job request sent by the Blaze engine executor to the Grid Manager. You can view filter by all tasks, or succeeded tasks, running tasks, or failed tasks.
- Grid segment. Part of a grid mapping that is contained in a grid task.
- Tasklet. A partition of a grid segment that runs on a separate DTM.
- Tasklet Attempts. The number of recovery attempts to restart a tasklet.

The Blaze Job Monitor displays the task history for mapping jobs. You can monitor properties for a task such as name, start time, end time, or state of the task. You can also view log events. If you filter mapping jobs by grid segment, you can mouse over a grid segment to view the logical name of the segment.

By default, the Blaze Job Monitor automatically refreshes the list of tasks every five seconds and reverts to the first page that displays tasks. Disable auto refresh if you want to browse through multiple pages. To turn off automatic refresh, click Action > Disable Auto Refresh.

The Blaze Job Monitor displays the first 100,000 grid tasks run in the past seven days. The Blaze Job Monitor displays the grid segments, tasklets, and tasklet attempts for grid tasks that are running and grid tasks that were accessed in the last 30 minutes.

### Monitoring a Mapping

You can monitor a mapping that runs in the Hadoop environment.

1. In the Administrator tool, click the Monitor tab.
2. Select the Execution Statistics view.
3. In the Navigator, choose to open an ad hoc job or a deployed mapping job.
   - To choose an ad hoc job, expand a Data Integration Service and click Ad Hoc Jobs.
   - To choose a deployed mapping job, expand an application and click Deployed Mapping Jobs.
   The list of jobs appears in the contents panel.
4. Click a job to view its properties.
   The contents panel shows the default Properties view for the job. For a Blaze engine mapping, the Blaze engine monitoring URL appears in the general properties in the details panel. The monitoring URL is a link to the YARN web user interface for Spark jobs.
5. Choose a view in the contents panel to view more information about the job:
   - To view the execution plan for the mapping, select the Execution Plan view.
   - To view the summary statistics for a job, click the Summary Statistics view.
   - To view the detailed statistics for a job, click the Detailed Statistics view.

### Hadoop Environment Logs

The Data Integration Service generates log events when you run a mapping in the Hadoop environment.

You can view logs for the Blaze engine, the Spark engine, or the Hive on MapReduce engine. You can view log events relating to different types of errors such as Hadoop connection failures, Hive query failures, Hive command failures, or other Hadoop job failures.
You can view the Scala code that the Logical Data Translation Generator generates from the Informatica mapping.

You can view reject files in the reject file directory specified for the Data Integration Service.

YARN Web User Interface

You can view the applications that ran on a cluster in the YARN web user interface. Click the Monitoring URL for Blaze, Hive, or for Spark jobs to access the YARN web user interface.

Blaze, Spark, and Hive engines run on the Hadoop cluster that you configure in the Hadoop connection. The YARN web user interface shows each job that the engine runs as a YARN application.

The following image shows the Application Monitoring page of the YARN web user interface:

![Application Monitoring page of the YARN web user interface]

The **Application Type** indicates which engine submitted the YARN application.

The **Application ID** is the unique identifier for the application. The Application ID is a URL a link to the application summary. The URL is the same as the **Monitoring URL** in the Administrator tool.

Click the **Logs** URL in the application summary to view the application logs on the Hadoop cluster.

Blaze Engine Logs

The Blaze engine logs appear in the LDTM log and in the Hadoop cluster logs.

You can find the information about Blaze engine log events in the following log file files:

**LDTM log**

The LDTM logs the results of the Blaze engines execution plan run for the mapping. You can view the LDTM log from the Developer tool or the Monitoring tool for a mapping job.

**Blaze component and tasklet logs**

The Blaze engine stores tasklet and Blaze component log events in temporary and permanent directories on the Hadoop cluster. The log file directories are specified by properties in the hadoopEnv.properties file located in the following location for each Hadoop distribution:

```
<Informatica Installation directory>/services/shared/hadoop/<distribution directory>/infaConf
```
In the Blaze Job Monitor, select a job from the list of jobs. In the row for the selected job, click the Spark Engine Logs. In the YARN web user interface, click an application ID to view the Spark Engine Logs. Click the application Spark Engine Logs.

The Spark engine logs appear in the LDTM log.

You can view logs for a Blaze mapping from the Blaze Job Monitor.

1. In the Blaze Job Monitor, select a job from the list of jobs.
2. In the row for the selected job, click the Logs link. The log events appear in another browser window.

Viewing Logs in the Blaze Job Monitor

You can view logs for a Blaze mapping from the Blaze Job Monitor.

Spark Engine Logs

The Spark engine logs appear in the LDTM log.

The LDTM logs the results of the Spark engines execution plan run for the mapping. You can view the LDTM log from the Developer tool or the Monitoring tool for a mapping job. The log for the Spark engine shows the steps to translate the mapping to an internal format, steps to optimize the mapping, steps to render the mapping to Spark code, and the steps to submit the code to the Spark executor. The logs also show the Scala code that the Logical Data Translation Generator creates from the mapping logic.

Viewing Spark Logs

You can view logs for a Spark mapping from the YARN web user interface.

1. In the YARN web user interface, click an application ID to view. Click the application Details. Click the Logs URL in the application details to view the logs for the application instance. The log events appear in another browser window.
Hive Engine Logs

The Hive engine logs appear in the LDTM log and the Hive session log.

You can find the information about Hive engine log events in the following log files:

**LDTM log**

The LDTM logs the results of the Hive queries run for the mapping. You can view the LDTM log from the Developer tool or the Administrator tool for a mapping job.

**Hive session log**

For every Hive script in the Hive execution plan for a mapping, the Data Integration Service opens a Hive session to run the Hive queries. A Hive session updates a log file in the following directory on the Data Integration Service node: `<InformaticaInstallationDir>/tomcat/bin/disTemp/`. The full path to the Hive session log appears in the LDTM log.

Viewing Hadoop Environment Logs in the Administrator Tool

You can view log events for a Blaze or Hive mapping from the Monitor tab of the Administrator tool.

1. In the Administrator tool, click the **Monitor** tab.
2. Select the **Execution Statistics** view.
3. In the Navigator, choose to open an ad hoc job or a deployed mapping job.
   - To choose an ad hoc job, expand a Data Integration Service and click **Ad Hoc Jobs**.
   - To choose a deployed mapping job, expand an application and click **Deployed Mapping Jobs**. The list of jobs appears in the contents panel.
4. Click **Actions > View Logs for Selected Object** to view the run-time logs for the mapping.

   The log file shows the results of the Hive queries and Blaze engine queries run by the Data Integration Service. This includes the location of Hive session logs and Hive session history file.

Optimization for the Hadoop Environment

You can optimize the Hadoop environment and the Hadoop cluster to increase performance.

You can optimize the Hadoop environment and the Hadoop cluster in the following ways:

**Configure a highly available Hadoop cluster**

You can configure the Data Integration Service and the Developer tool to read from and write to a highly available Hadoop cluster. The steps to configure a highly available Hadoop cluster depend on the type of Hadoop distribution. For more information about configuration steps for a Hadoop distribution, see the *Informatica Big Data Management Installation and Configuration Guide*.

**Compress data on temporary staging tables**

You can enable data compression on temporary staging tables to increase mapping performance.

**Run mappings on the Blaze engine**

Run mappings on the highly available Blaze engine. The Blaze engine enables restart and recovery of grid tasks and tasklets by default.
Perform parallel sorts

When you use a Sorter transformation in a mapping, the Data Integration Service enables parallel sorting by default when it pushes the mapping logic to the Hadoop cluster. Parallel sorting improves mapping performance with some restrictions.

Partition Joiner transformations

When you use a Joiner transformation in a Blaze engine mapping, the Data Integration Service can apply map-side join optimization to improve mapping performance. The Data Integration Service applies map-side join optimization if the master table is smaller than the detail table. When the Data Integration Service applies map-side join optimization, it moves the data to the Joiner transformation without the cost of shuffling the data.

Truncate partitions in a Hive target

You can truncate partitions in a Hive target to increase performance. To truncate partitions in a Hive target, you must choose to both truncate the partition in the Hive target and truncate the target table. You can enable data compression on temporary staging tables to optimize performance.

Blaze Engine High Availability

The Blaze engine is a highly available engine that determines the best possible recovery strategy for grid tasks and tasklets.

Based on the size of the grid task, the Blaze engine attempts to apply the following recovery strategy:

- No high availability. The Blaze engine not apply a recovery strategy.
- Full restart. Restarts the grid task.

Truncating Partitions in a Hive Target

To truncate partitions in a Hive target, you must edit the write properties for the customized data object that you created for the Hive target in the Developer tool.

1. Open the customized data object in the editor.
2. To edit write properties, select the Input transformation in the Write view, and then select the Advanced properties.
3. Select Truncate Hive Target Partition.
4. Select Truncate target table.

Enabling Data Compression on Temporary Staging Tables

To optimize performance when you run a mapping in the Hadoop environment, you can enable data compression on temporary staging tables. When you enable data compression on temporary staging tables, mapping performance might increase.

To enable data compression on temporary staging tables, complete the following steps:

1. Configure the Hive connection to use the codec class name that the Hadoop cluster uses to enable compression on temporary staging tables.
2. Configure the Hadoop cluster to enable compression on temporary staging tables.
Hadoop provides following compression libraries for the following compression codec class names:

<table>
<thead>
<tr>
<th>Compression Library</th>
<th>Codec Class Name</th>
<th>Performance Recommendation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Zlib</td>
<td>org.apache.hadoop.io.compress.DefaultCodec</td>
<td>n/a</td>
</tr>
<tr>
<td>Gzip</td>
<td>org.apache.hadoop.io.compress.GzipCodec</td>
<td>n/a</td>
</tr>
<tr>
<td>LZO</td>
<td>com.hadoop.compression.lzo.LzoCodec</td>
<td>n/a</td>
</tr>
</tbody>
</table>

Step 1. Configure the Hive Connection to Enable Data Compression on Temporary Staging Tables

Use the Administrator tool or the Developer tool to configure the Hive connection. You can edit the Hive connection properties to configure the codec class name that enables data compression on temporary staging tables.

1. In the Hive connection properties, edit the properties to run mappings in a Hadoop cluster.
2. Select **Temporary Table Compression Codec**.
3. Choose to select a predefined codec class name or enter a custom codec class name.
   - To select a predefined codec class name, select a compression library from the list.
   - To enter a custom codec class name, select custom from the list and enter the codec class name that matches the codec class name in the Hadoop cluster.

Step 2. Configure the Hadoop Cluster to Enable Compression on Temporary Staging Tables

To enable compression on temporary staging tables, you must install a compression codec on the Hadoop cluster.

For more information about how to install a compression codec, refer to the Apache Hadoop or Hive documentation.

1. Verify that the native libraries for the compression codec class name are installed on every node on the cluster.
2. To include the compression codec class name that you want to use, update the property io.compression.codecs in core-site.xml. The value for this property is a comma separated list of all the codec class names supported on the cluster.
3. Verify that the Hadoop-native libraries for the compression codec class name that you want to use are installed on every node on the cluster.
4. Verify that the LD_LIBRARY_PATH variable on the Hadoop cluster includes the locations of both the native and Hadoop-native libraries where you installed the compression codec.
Parallel Sorting

To improve mapping performance, the Data Integration Service enables parallel sorting by default in a mapping that has a Sorter transformation and a flat file target.

The Data Integration Service enables parallel sorting for mappings in a Hadoop environment based on the following rules and guidelines:

- The mapping does not include another transformation between the Sorter transformation and the target.
- The data type of the sort keys does not change between the Sorter transformation and the target.
- Each sort key in the Sorter transformation must be linked to a column in the target.

Troubleshooting a Mapping in a Hadoop Environment

When I run a mapping with a Hive source or a Hive target on a different cluster, the Data Integration Service fails to push the mapping to Hadoop with the following error: Failed to execute query [exec0_query_6] with error code [10], error message [FAILED: Error in semantic analysis: Line 1:181 Table not found customer_eur], and SQL state [42000].

When you run a mapping in a Hadoop environment, the Hive connection selected for the Hive source or Hive target, and the mapping must be on the same Hive metastore.

When I run a mapping with MapR 2.1.2 distribution that processes large amounts of data, monitoring the mapping from the Administrator tool stops.

You can check the Hadoop task tracker log to see if there a timeout that results in Hadoop job tracker losing connection. To continuously monitor the mapping from the Administrator tool, increase the virtual memory to 640 MB in the hadoopEnv.properties file. The default is 512 MB. For example, infapdo.java.opts=-Xms640M -XX:GCTimeRatio=34 -XX:+UseConcMarkSweepGC -XX:+UseParNewGC -XX:ParallelGCThreads=2 -XX:NewRatio=2 -Djava.library.path=/HADOOP_NODE_INFA/Home/services/shared/bin:/HADOOP_NODE_HADOOP_DIST/lib/native/Linux-amd64-64 -Djava.security.egd=file:/dev/./urandom -Dmapr.library.flatclass

When I run a mapping with a Hadoop distribution on MapReduce 2, the Administrator tool shows the percentage of completed reduce tasks as 0% instead of 100%.

Verify that the Hadoop jobs have reduce tasks.

When the Hadoop distribution is on MapReduce 2 and the Hadoop jobs do not contain reducer tasks, the Administrator tool shows the percentage of completed reduce tasks as 0%.

When the Hadoop distribution is on MapReduce 2 and the Hadoop jobs contain reducer tasks, the Administrator tool shows the percentage of completed reduce tasks as 100%.
CHAPTER 4

Mapping Objects in a Hadoop Environment

This chapter includes the following topics:

• Sources in a Hadoop Environment, 68
• Targets in a Hadoop Environment, 72
• Transformations in a Hadoop Environment, 75
• Function and Data Type Processing, 81

Sources in a Hadoop Environment

You can push a mapping to the Hadoop environment that includes a source from the native environment or from the Hadoop environment. Some sources have limitations when you reference them in the Hadoop environment.

You can run mappings with the following sources in a Hadoop environment:

• Flat file (native)
• HBase
• HDFS complex file
• HDFS flat file
• Hive
• IBM DB2
• Netezza
• ODBC
• Oracle
• Sqoop sources
• Teradata

When a mapping runs in the Hadoop environment, an HDFS source or a Hive source cannot reside on a remote cluster. A remote cluster is a cluster that is remote from the machine that the Hadoop connection references in the mapping.
Flat File Sources

A mapping that is running in a Hadoop environment can read a flat file source from a native environment.

Consider the following limitations when you configure the mapping to read a flat file source:

- You cannot use an indirect source type.
- The row size in a flat file source cannot exceed 190 MB.
- You cannot use a command to generate or to transform flat file data and send the output to the flat file reader at run time.

Generate the Source File Name

You can generate the source file name for the flat file data object. The content of the file name column remains consistent across different modes of execution.

When you push processing to the specific engine for the required file types, the file name column returns the path based on the following formats:

<table>
<thead>
<tr>
<th>Pushdown Processing Engine</th>
<th>Type of Files Processes</th>
<th>Returned Path</th>
</tr>
</thead>
<tbody>
<tr>
<td>Hive</td>
<td>HDFS source files</td>
<td><code>&lt;staged path&gt;&lt;HDFS file path&gt;</code>&lt;br&gt;For example, hdfs://host name:port/hive/warehouse/ff.txt</td>
</tr>
<tr>
<td>Hive</td>
<td>Flat files in the local system</td>
<td><code>&lt;local file path&gt;</code>&lt;br&gt;For example, /home/devbld/Desktop/ff.txt</td>
</tr>
<tr>
<td>Blaze</td>
<td>Flat files in the local system</td>
<td><code>&lt;staged path&gt;&lt;local file path&gt;</code>&lt;br&gt;For example, hdfs://host name:port/hive/warehouse/home/devbld/Desktop/ff.txt</td>
</tr>
<tr>
<td>Spark</td>
<td>HDFS source files</td>
<td><code>hdfs://&lt;host name&gt;:&lt;port&gt;/&lt;file name path&gt;</code>&lt;br&gt;For example, hdfs://host name:port/hive/warehouse/ff.txt</td>
</tr>
<tr>
<td>Spark</td>
<td>Flat files in the local system</td>
<td><code>&lt;local file path&gt;</code>&lt;br&gt;For example, /home/devbld/Desktop/ff.txt</td>
</tr>
</tbody>
</table>

The file name column returns the content in the following format for High-Availability cluster: `hdfs://<host name>/<file name path>`

For example, hdfs://irldv:5008/hive/warehouse/ff.txt
Hive Sources

You can include Hive sources in an Informatica mapping that runs in a Hadoop environment.

Consider the following limitations when you configure a Hive source in a mapping that runs in a Hadoop environment:

- The Data Integration Service can run pre-mapping SQL commands against the source database before it reads from a Hive source. When you run a mapping with a Hive source in a Hadoop environment, references to a local path in pre-mapping SQL commands are relative to the Data Integration Service node. When you run a mapping with a Hive source in the native environment, references to local path in pre-mapping SQL commands are relative to the Hive server node.

- A mapping fails to validate when you configure post-mapping SQL commands. The Data Integration Service does not run post-mapping SQL commands against a Hive source.

- A mapping fails to run when you have Unicode characters in a Hive source definition.

- The third-party Hive JDBC driver does not return the correct precision and scale values for the Decimal data type. As a result, when you import Hive tables with a Decimal data type into the Developer tool, the Decimal data type precision is set to 38 and the scale is set to 0. Consider the following configuration rules and guidelines based on the version of Hive:
  - Hive 0.11. Accept the default precision and scale for the Decimal data type in the Developer tool.
  - Hive 0.12. Accept the default precision and scale for the Decimal data type in the Developer tool.
  - Hive 0.12 with Cloudera CDH 5.0. You can configure the precision and scale fields for source columns with the Decimal data type in the Developer tool.
  - Hive 0.13 and above. You can configure the precision and scale fields for source columns with the Decimal data type in the Developer tool.
  - Hive 0.14 or above. The precision and scale used for the Decimal data type in the Hive database also appears in the Developer tool.

A mapping that runs with the Spark engine can have partitioned Hive source tables and bucketed sources.

Consider the following limitations when you configure a Hive source in a mapping that runs with the Blaze engine:

- Hive sources for a Blaze mapping include the TEXT, Sequence, Avro, RC, ORC, and Parquet storage formats.

- The TEXT storage format in a Hive source for a Blaze mapping can support ASCII characters as column delimiters and the newline characters as a row separator. You cannot use hex values of ASCII characters. For example, use a semicolon (;) instead of 3B.

- You cannot define an SQL override in the Hive source for a Blaze mapping.

- Hive sources for a Blaze mapping cannot use bucketed tables.

Complex File Sources

A mapping that is running in a Hadoop environment can process complex files.

You can read files from the local file system or from HDFS. To read large volumes of data, you can connect a complex file source to read data from a directory of files that have the same format and properties. You can read compressed binary files.

A mapping that runs on a Blaze engine or a Hive engine can contain a Data Processor transformation. You can include a complex file reader object without a Data Processor transformation to read complex files that are flat files. If the complex file is a hierarchical file, you must connect the complex file reader object to a Data Processor transformation.
The following table shows the complex files that a mapping can process in the Hadoop environment:

<table>
<thead>
<tr>
<th>File Type</th>
<th>Format</th>
<th>Blaze Mode</th>
<th>Spark Mode</th>
<th>Hive Mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>Avro</td>
<td>Flat</td>
<td>Supported</td>
<td>Supported</td>
<td>Supported</td>
</tr>
<tr>
<td>Avro</td>
<td>Hierarchical</td>
<td>Supported*</td>
<td>Not supported</td>
<td>Supported*</td>
</tr>
<tr>
<td>JSON</td>
<td>Flat</td>
<td>Supported*</td>
<td>Not supported</td>
<td>Supported*</td>
</tr>
<tr>
<td>JSON</td>
<td>Hierarchical</td>
<td>Supported*</td>
<td>Not supported</td>
<td>Supported*</td>
</tr>
<tr>
<td>ORC</td>
<td>Flat</td>
<td>Supported*</td>
<td>Supported</td>
<td>Supported*</td>
</tr>
<tr>
<td>ORC</td>
<td>Hierarchical</td>
<td>Supported*</td>
<td>Not supported</td>
<td>Supported*</td>
</tr>
<tr>
<td>Parquet</td>
<td>Flat</td>
<td>Supported</td>
<td>Supported</td>
<td>Supported</td>
</tr>
<tr>
<td>Parquet</td>
<td>Hierarchical</td>
<td>Supported*</td>
<td>Not supported</td>
<td>Supported*</td>
</tr>
<tr>
<td>XML</td>
<td>Flat</td>
<td>Supported*</td>
<td>Not supported</td>
<td>Supported*</td>
</tr>
<tr>
<td>XML</td>
<td>Hierarchical</td>
<td>Supported*</td>
<td>Not supported</td>
<td>Supported*</td>
</tr>
</tbody>
</table>

* The complex file reader object must be connected to a Data Processor transformation.

Relational Sources

Relational sources are valid in mappings that run in a Hadoop environment if you use the Hive engine or the Blaze engine. The Spark engine cannot run mappings with relational resources.

The Data Integration Service does not run pre-mapping SQL commands or post-mapping SQL commands against relational sources. You cannot validate and run a mapping with PreSQL or PostSQL properties for a relational source in a Hadoop environment.

The Data Integration Service can use multiple partitions to read from the following relational sources:

- IBM DB2
- Oracle

**Note:** You do not have to set maximum parallelism for the Data Integration Service to use multiple partitions in the Hadoop environment.

Sqoop Sources

Sqoop sources are valid in mappings in a Hadoop environment if you use the Hive engine.

You can include a JDBC-compliant database as a Sqoop source in an Informatica mapping that runs in a Hadoop environment:

For example, you can include the following sources in a Sqoop mapping:

- Aurora
- Greenplum
- IBM DB2
- IBM DB2 for z/OS
• Microsoft SQL Server
• Netezza
• Oracle
• Teradata

If you create a password file to access a database, to run the mapping successfully, you must ensure that the password file exists on HDFS.

Consider the following restrictions when you configure a Sqoop source in a mapping:
• If you override the default query in the mapping with an advanced query, the Sqoop import process fails.
• If you specify a sort condition in the mapping, the Data Integration Service ignores the Order By condition.

### Targets in a Hadoop Environment

You can push a mapping to the Hadoop environment that includes a target from the native environment or from the Hadoop environment. Some sources have limitations when you reference them in the Hadoop environment.

You can run mappings with the following targets in a Hadoop environment:
• Complex files
• Flat file (native)
• Greenplum
• HBase
• HDFS flat file
• Hive
• IBM DB2
• Netezza
• ODBC
• Oracle
• Sqoop targets
• Teradata

A mapping that runs with the Spark engine can have partitioned Hive target tables but it cannot have bucketed targets.

When a mapping runs in the Hadoop environment, an HDFS target or a Hive target cannot reside on a remote cluster. A remote cluster is a cluster that is remote from the machine that the Hadoop connection references in the mapping.
Flat File Targets

A mapping that is running in a Hadoop environment can write to a flat file target that is in a native environment.

Consider the following limitations when you configure a flat file target in a mapping that runs in a Hadoop environment:

- The Data Integration Service truncates the target files and reject files before writing the data. When you use a flat file target, you cannot append output data to target files and reject files.
- The Data Integration Service can write to a file output for a flat file target. When you have a flat file target in a mapping, you cannot write data to a command.

HDFS Flat File Targets

HDFS flat file targets are valid in mappings that run in a Hadoop environment.

When you use a HDFS flat file target in a mapping, you must specify the full path that includes the output file directory and file name. The Data Integration Service might generate multiple output files in the output directory when you run the mapping in a Hadoop environment.

Hive Targets

A mapping that is running in a Hadoop environment can write to a Hive target.

Consider the following limitations when you configure a Hive target in a mapping that runs in a Hadoop environment:

- The Data Integration Service does not run pre-mapping or post-mapping SQL commands against a Hive target. You cannot validate and run a mapping with PreSQL or PostSQL properties for a Hive target.
- A mapping fails to run if the Hive target definition differs in the number and order of the columns from the relational table in the Hive database.
- A mapping fails to run when you use Unicode characters in a Hive target definition.
- You must truncate the target table to overwrite data to a Hive table with Hive version 0.7. The Data Integration Service ignores write, update override, delete, insert, and update strategy properties when it writes data to a Hive target.
- The Data Integration Service can truncate the partition in the Hive target in which the data is being inserted. You must choose to both truncate the partition in the Hive target and truncate the target table.
- You cannot perform update or delete on Hive targets for a Blaze engine mapping.

Complex File Targets

A mapping that is running in a Hadoop environment can process complex files.

The following table shows the complex files that a mapping can process in the Hadoop environment:

<table>
<thead>
<tr>
<th>File Type</th>
<th>Format</th>
<th>Blaze Mode</th>
<th>Spark Mode</th>
<th>Hive Mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>Avro</td>
<td>Flat</td>
<td>Supported</td>
<td>Supported</td>
<td>Supported</td>
</tr>
<tr>
<td>Avro</td>
<td>Hierarchical</td>
<td>Supported*</td>
<td>Not supported</td>
<td>Supported*</td>
</tr>
<tr>
<td>JSON</td>
<td>Flat</td>
<td>Supported*</td>
<td>Not supported</td>
<td>Supported*</td>
</tr>
<tr>
<td>File Type</td>
<td>Format</td>
<td>Blaze Mode</td>
<td>Spark Mode</td>
<td>Hive Mode</td>
</tr>
<tr>
<td>-----------</td>
<td>--------------</td>
<td>------------</td>
<td>----------------</td>
<td>---------------</td>
</tr>
<tr>
<td>JSON</td>
<td>Hierarchical</td>
<td>Supported*</td>
<td>Not supported</td>
<td>Supported*</td>
</tr>
<tr>
<td>ORC</td>
<td>Flat</td>
<td>Supported*</td>
<td>Supported</td>
<td>Supported*</td>
</tr>
<tr>
<td>ORC</td>
<td>Hierarchical</td>
<td>Supported*</td>
<td>Not supported</td>
<td>Supported*</td>
</tr>
<tr>
<td>Parquet</td>
<td>Flat</td>
<td>Supported</td>
<td>Supported</td>
<td>Supported</td>
</tr>
<tr>
<td>Parquet</td>
<td>Hierarchical</td>
<td>Supported*</td>
<td>Not supported</td>
<td>Supported*</td>
</tr>
<tr>
<td>XML</td>
<td>Flat</td>
<td>Supported*</td>
<td>Not supported</td>
<td>Supported*</td>
</tr>
<tr>
<td>XML</td>
<td>Hierarchical</td>
<td>Supported*</td>
<td>Not supported</td>
<td>Supported*</td>
</tr>
</tbody>
</table>

* The complex file writer object must be connected to a Data Processor transformation.

Relational Targets

Relational targets are valid in mappings in a Hadoop environment if you use the Hive or Blaze engine. The Spark engine cannot run mappings with relational targets.

The Data Integration Service does not run pre-mapping SQL commands or post-mapping SQL commands against relational targets in a Hadoop environment. You cannot validate and run a mapping with PreSQL or PostSQL properties for a relational target in a Hadoop environment.

The Data Integration Service can use multiple partitions to write to the following relational targets:

- IBM DB2
- Oracle

**Note:** You do not have to set maximum parallelism for the Data Integration Service to use multiple partitions in the Hadoop environment.

Sqoop Targets

Sqoop targets are valid in mappings in a Hadoop environment if you use the Hive engine.

You can include a JDBC-compliant database as a Sqoop target in an Informatica mapping that runs in a Hadoop environment:

For example, you can include the following targets in a Sqoop mapping:

- Aurora
- Greenplum
- IBM DB2
- IBM DB2 for z/OS
- Microsoft SQL Server
- Netezza
- Oracle
- Teradata
You can insert data. You cannot update or delete data in a target. If you configure update arguments, the Sqoop program ignores them.

If you create a password file to access a database, to run the mapping successfully, you must ensure that the password file exists on HDFS. If a column name contains a special character, the Sqoop export process fails.

Transformations in a Hadoop Environment

Due to the differences between native environment and Hadoop environment only certain transformations are valid or valid with restrictions in the Hadoop environment. The Data Integration Service does not process transformations that contain functions, expressions, data types, and variable fields that are not valid in a Hadoop environment.

The following table lists transformations and levels of support for different engines in a Hadoop environment:

<table>
<thead>
<tr>
<th>Transformation</th>
<th>Blaze Engine</th>
<th>Spark Engine</th>
<th>Hive Engine</th>
</tr>
</thead>
<tbody>
<tr>

Transformation Support on the Blaze Engine

Some restrictions and guidelines apply to processing transformations on the Blaze engine.

**Note:** For the latest information about transformation support on the Blaze engine, refer to the PDF documentation on Informatica Network. To access Informatica Network, visit [https://network.informatica.com](https://network.informatica.com).

The following table describes rules and guidelines for processing transformations on the Blaze engine:

<table>
<thead>
<tr>
<th>Transformation</th>
<th>Blaze Engine</th>
<th>Spark Engine</th>
<th>Hive Engine</th>
</tr>
</thead>
<tbody>
<tr>
<td>Merge</td>

Transformation Support on the Blaze Engine

Some restrictions and guidelines apply to processing transformations on the Blaze engine.

**Note:** For the latest information about transformation support on the Blaze engine, refer to the PDF documentation on Informatica Network. To access Informatica Network, visit [https://network.informatica.com](https://network.informatica.com).

The following table describes rules and guidelines for processing transformations on the Blaze engine:

<table>
<thead>
<tr>
<th>Transformation</th>
<th>Rules and Guidelines</th>
</tr>
</thead>
<tbody>
<tr>
<td>Address Validator</td>
<td>The Address Validator transformation cannot generate a certification report.</td>
</tr>
</tbody>
</table>
| Aggregator            | Mapping validation fails in the following situations:  
: The transformation contains stateful variable ports.  
: The transformation contains unsupported functions in an expression. |
| Case Converter        | Supported without restrictions. |
| Comparison            | Supported without restrictions. |
| Data Processor        | Mapping validation fails in the following situations:  
: The transformation has more than one input port.  
: The input port is not a binary port.  
: The transformation is not enabled for partitioning. |
<p>| Decision              | Supported without restrictions. |</p>
<table>
<thead>
<tr>
<th>Transformation</th>
<th>Rules and Guidelines</th>
</tr>
</thead>
</table>
| Expression     | Mapping validation fails in the following situations:  
|                | - The transformation contains stateful variable ports.  
|                | - The transformation contains unsupported functions in an expression.  
|                | An Expression transformation with a user-defined function returns a null value for rows that have an exception error in the function. |
| Filter         | Supported without restrictions. |
| Java           | Supported without restrictions. |
| Joiner         | Mapping validation fails in the following situations:  
|                | - The transformation contains an inequality join. |
| Key Generator  | Supported without restrictions. |
| Labeler        | Supported without restrictions. |
| Lookup         | Mapping validation fails in the following situations:  
|                | - The cache is configured to be shared, named, persistent, dynamic, or uncached. The cache must be a static cache.  
|                | - The lookup is a relational Hive data source. |
| Match          | Mapping validation fails in the following situations:  
|                | - The mapping specifies an identity match type.  
|                | A Match transformation generates cluster ID values differently in native and Hadoop environments. In a Hadoop environment, the transformation appends a group ID value to the cluster ID. |
| Merge          | Supported without restrictions. |
| Normalizer     | Supported without restrictions. |
| Parser         | Supported without restrictions. |
| Rank           | Supported without restrictions. |
| Router         | Supported without restrictions. |
| Sequence Generator | Mapping validation fails in the following situations:  
|                | - The reset property for the transformation is enabled.  
|                | If you want the Data Integration Service to reset the sequence data object to the start value for each mapping run, then you must run the mapping in the native environment. |
| Sorter         | Supported without restrictions. |
| Standardizer   | Supported without restrictions. |
| Union          | Supported without restrictions. |
| Weighted Average | Supported without restrictions. |

Transformations not listed in this table are not supported.
Transformation Support on the Spark Engine

Some restrictions and guidelines apply to processing transformations on the Spark engine.

</table>

*Transformations not listed in this table are not supported.*

Transformation Support on the Hive Engine

Some restrictions and guidelines apply to processing transformations on the Hive engine.
The following table describes rules and guidelines for processing transformations on the Hive engine.

<table>
<thead>
<tr>
<th>Transformation</th>
<th>Rules and Guidelines</th>
</tr>
</thead>
<tbody>
<tr>
<td>Address Validator</td>
<td>The Address Validator transformation cannot generate a certification report.</td>
</tr>
</tbody>
</table>
| Aggregator      | Mapping validation fails in the following situations:  
- The transformation contains stateful variable ports.  
- The transformation contains unsupported functions in an expression.                                                                                                                                                                                                                                                                 |
| Case Converter  | Supported without restrictions.                                                                                                                                                                                                                                                                                                                                 |
| Comparison      | Supported without restrictions.                                                                                                                                                                                                                                                                                                                                 |
| Consolidation   | The Consolidation transformation might process data differently in the native environment and in a Hadoop environment.  
The transformation might demonstrate the following differences in behavior:  
- The transformation might process records in a different order in each environment.  
- The transformation might identify a different record as the survivor in each environment.                                                                                                                                                                                                 |
| Data Masking    | Mapping validation fails in the following situations:  
- The transformation is configured for repeatable expression masking.  
- The transformation is configured for unique repeatable substitution masking.                                                                                                                                                                                                 |
| Data Processor  | Mapping validation fails in the following situations:  
- The transformation contains more than one input port.  
- The transformation contains pass-through ports.                                                                                                                                                                                                                                                                 |
| Decision        | Supported without restrictions.                                                                                                                                                                                                                                                                                                                                 |
| Expression      | Mapping validation fails in the following situations:  
- The transformation contains stateful variable ports.  
- The transformation contains unsupported functions in an expression.  
An Expression transformation with a user-defined function returns a null value for rows that have an exception error in the function.                                                                                                                                                                                                 |
| Filter          | Supported without restrictions.                                                                                                                                                                                                                                                                                                                                 |
| Java            | You must copy external .jar files that a Java transformation requires to the Informatica installation directory in the Hadoop cluster nodes at the following location: \[\$SHADOOP_NODE_INFA_HOME\]/services/shared/jars/platform/dtm/  
You can optimize the transformation for faster processing when you enable an input port as a partition key and sort key. The data is partitioned across the reducer tasks and the output is partially sorted.  
The following restrictions apply to the Transformation Scope property:  
- The value Transaction for transformation scope is not valid.  
- If transformation scope is set to Row, a Java transformation is run by mapper script.  
- If you enable an input port for partition Key, the transformation scope is set to All Input. When the transformation scope is set to All Input, a Java transformation is run by the reducer script and you must set at least one input field as a group-by field for the reducer key.  
You can enable the Stateless advanced property when you run mappings in a Hadoop environment.  
The Java code in the transformation cannot write output to standard output when you push transformation logic to Hadoop. The Java code can write output to standard error which appears in the log files.                                                                                                                                                                                                 |
| Joiner          | Mapping validation fails in the following situations:  
- The transformation contains an inequality join.                                                                                                                                                                                                                                                                                                                                 |
<p>| Labeler         | Supported without restrictions.                                                                                                                                                                                                                                                                                                                                 |</p>

| **Lookup**    | Mapping validation fails in the following situations:  
- The cache is configured to be shared, named, persistent, dynamic, or uncached. The cache must be a static cache.  
- The lookup is a relational Hive data source.  
Mappings fail in the following situations:  
- The lookup is unconnected.  
If you add a data object that uses Sqoop as a Lookup transformation in a mapping, the Data Integration Service does not run the mapping through Sqoop. It runs the mapping through JDBC.  
When you run a mapping that contains a Lookup transformation, the Data Integration Service creates lookup cache .jar files. Hive copies the lookup cache .jar files to the following temporary directory: /tmp/<user_name>/hive_resources. The Hive parameter hive.downloaded.resources.dir determines the location of the temporary directory. You can delete the lookup cache .jar files specified in the LDTM log after the mapping completes to retrieve disk space. |
| **Match**     | Mapping validation fails in the following situations:  
- The transformation specifies an identity match type.  
A Match transformation generates cluster ID values differently in native and Hadoop environments. In a Hadoop environment, the transformation appends a group ID value to the cluster ID. |
| **Merge**     | Supported without restrictions. |
| **Parser**    | Supported without restrictions. |
| **Rank**      | Mapping validation fails in the following situations:  
- Case sensitivity is disabled. |
| **Router**    | Supported without restrictions. |
| **Sorter**    | Mapping validation fails in the following situations:  
- Case sensitivity is disabled.  
The Data Integration Service logs a warning and ignores the Sorter transformation in the following situations:  
- There is a type mismatch between the Sorter transformation and the target.  
- The transformation contains sort keys that are not connected to the target.  
- The Write transformation is not configured to maintain row order.  
- The transformation is not directly upstream from the Write transformation.  
The Data Integration Service treats null values as high, even if you configure the transformation to treat null values as low. |
| **Standardizer** | Supported without restrictions. |
| **SQL**       | Mapping validation fails in the following situations:  
- The mapping also contains a Hive source or target. |
| **Union**     | Supported without restrictions. |
Transformation | Rules and Guidelines
---|---
Update Strategy | Mapping validation fails in the following situations:
- The transformation is connected to more than one target.
- The transformation is not connected directly to the target.
The mapping fails in the following situations:
- The target is not ORC bucketed.
- The target is ORC bucketed on all columns.
Compile validation errors occur and the mapping execution stops in the following situations:
- The target is not a Hive target on the same cluster.
- The Hive version is earlier than 0.14.
- A primary key is not configured.
The Hive engine performs Update as Update even if the transformation is configured to Update as Insert or Update else Insert.
Weighted Average | Supported without restrictions.

*Transformations not listed in this table are not supported.*

**Function and Data Type Processing**

When you run a mapping in a Hadoop environment, the engine that runs the mapping might process Informatica functions and data types differently from the Data Integration Service. Some variations apply in the processing and validity of functions and data types because of differences between the environments. As a result, mapping results can vary.

**Rules and Guidelines for Spark Engine Processing**

Some restrictions and guidelines apply to processing Informatica functions on the Spark engine.

**Important:** When you push a mapping to the Hadoop environment, the engine that processes the mapping uses a set of rules different from the Data Integration Service. As a result, the mapping results can vary based on the rules that the engine uses. This topic contains some processing differences that Informatica discovered through internal testing and usage. Informatica does not test all the rules of the third-party engines and cannot provide an extensive list of the differences.

Consider the following rules and guidelines for function and data type processing on the Spark engine:

- The Spark engine and the Data Integration Service process overflow values differently. The Spark engine processing rules might differ from the rules that the Data Integration Service uses. As a result, mapping results can vary between the native and Hadoop environment when the Spark engine processes an overflow. Consider the following processing variation for Spark:
  - If an expression results in numerical errors, such as division by zero or SQRT of a negative number, it returns an infinite or an NaN value. In the native environment, the expression returns null values and the rows do not appear in the output.
• The Spark engine and the Data Integration Service process data type conversions differently. As a result, mapping results can vary between the native and Hadoop environment when the Spark engine performs a data type conversion. Consider the following processing variations for Spark:
  - The Spark engine ignores the scale argument of the TO_DECIMAL function. The function returns a value with the same scale as the input value.
  - When the scale of a double or decimal value is smaller than the configured scale, the Spark engine trims the trailing zeros.
  - The Spark engine cannot process dates to the nanosecond. It can return a precision for date/time data up to the microsecond.
• The Hadoop environment treats "\n" values as null values. If an aggregate function contains empty or NULL values, the Hadoop environment includes these values while performing an aggregate calculation.
• Mapping validation fails if you configure SYSTIMESTAMP with a variable value, such as a port name. The function can either include no argument or the precision to which you want to retrieve the timestamp value.
• The UUID4 function is supported only when used as an argument in UUID_UNPARSE or ENC_BASE64.
• The UUID_UNPARSE function is supported only when the argument is UUID4( ).

Rules and Guidelines for Hive Engine Processing

Some restrictions and guidelines apply to processing Informatica functions on the Hive engine.

Important: When you push a mapping to the Hadoop environment, the engine that processes the mapping uses a set of rules different from the Data Integration Service. As a result, the mapping results can vary based on the rules that the engine uses. This topic contains some processing differences that Informatica discovered through internal testing and usage. Informatica does not test all the rules of the third-party engines and cannot provide an extensive list of the differences.

Consider the following rules and guidelines for function and data type processing on the Hive engine:
• The Hive engine and the Data Integration Service process overflow values differently. The Hive engine processing rules might differ from the rules that the Data Integration Service uses. As a result, mapping results can vary between the native and Hadoop environment when the Hive engine processes an overflow. Consider the following processing variations for Hive:
  - Hive uses a maximum or minimum value for integer and bigint data when there is data overflow during data type conversion.
  - If an expression results in numerical errors, such as division by zero or SQRT of a negative number, it returns an infinite or an NaN value. In the native environment, the expression returns null values and the rows do not appear in the output.
• The Hive engine and the Data Integration Service process data type conversions differently. As a result, mapping results can vary between the native and Hadoop environment when the Hive engine performs a data type conversion. Consider the following processing variations for Hive:
  - The results of arithmetic operations on floating point types, such as Decimal, can vary up to 0.1 percent between the native environment and a Hadoop environment.
  - You can use high precision Decimal data type with Hive 0.11 and above. When you run mappings on the Hive engine, the Data Integration Service converts decimal values with a precision greater than 38 digits to double values. When you run mappings that do not have high precision enabled, the Data Integration Service converts decimal values to double values.
  - When the Data Integration Service converts a decimal with a precision of 10 and a scale of 3 to a string data type and writes to a flat file target, the results can differ between the native environment and a
Hadoop environment. For example, on the Hive engine, HDFS writes the output string for the decimal 19711025 with a precision of 10 and a scale of 3 as 1971. The Data Integration Service sends the output string for the decimal 19711025 with a precision of 10 and a scale of 3 as 1971.000.

- The results of arithmetic operations on floating point types, such as a Double, can vary up to 0.1 percent between the Data Integration Service and the Hive engine.

- When you run a mapping with a Hive target that uses the Double data type, the Data Integration Service processes the double data up to 17 digits after the decimal point.

- The Hadoop environment treats "/n" values as null values. If an aggregate function contains empty or NULL values, the Hadoop environment includes these values while performing an aggregate calculation.

- The UUID4 function is supported only when used as an argument in UUID_UNPARSE or ENC_BASE64.

- The UUID_UNPARSE function is supported only when the argument is UUID4( ).
Mappins in the Native Environment

This chapter includes the following topics:

- Mappings in the Native Environment Overview, 84
- Data Processor Mappings, 84
- HDFS Mappings, 85
- Hive Mappings, 86
- Social Media Mappings, 87

Mappings in the Native Environment Overview

You can run a mapping in the native environment. In the native environment, the Data Integration Service runs the mapping from the Developer tool. You can run standalone mappings or mappings that are a part of a workflow.

In the native environment, you can read and process data from large unstructured and semi-structured files, Hive, or social media web sites. You can include the following objects in the mappings:

- Hive sources
- Flat file sources or targets in the local system or in HDFS
- Complex file sources in the local system or in HDFS
- Data Processor transformations to process unstructured and semi-structured file formats
- Social media sources

Data Processor Mappings

The Data Processor transformation processes unstructured and semi-structured file formats in a mapping. It converts source data to flat CSV records that MapReduce applications can process.

You can configure the Data Processor transformation to process messaging formats, HTML pages, XML, and PDF documents. You can also configure it to transform structured formats such as ACORD, HIPAA, HL7, EDI-X12, EDIFACT, AFP, and SWIFT.
For example, an application produces hundreds of data files per second and writes the files to a directory. You can create a mapping that extracts the files from the directory, passes them to a Data Processor transformation, and writes the data to a target.

### HDFS Mappings

Create an HDFS mapping to read or write to HDFS.

You can read and write fixed-width and delimited file formats. You can read or write compressed files. You can read text files and binary file formats such as sequence file from HDFS. You can specify the compression format of the files. You can use the binary stream output of the complex file data object as input to a Data Processor transformation to parse the file.

You can define the following objects in an HDFS mapping:

- Flat file data object or complex file data object operation as the source to read data from HDFS.
- Transformations.
- Flat file data object as the target to write data to HDFS or any target.

Validate and run the mapping. You can deploy the mapping and run it or add the mapping to a Mapping task in a workflow.

### HDFS Data Extraction Mapping Example

Your organization needs to analyze purchase order details such as customer ID, item codes, and item quantity. The purchase order details are stored in a semi-structured compressed XML file in HDFS. The hierarchical data includes a purchase order parent hierarchy level and a customer contact details child hierarchy level. Create a mapping that reads all the purchase records from the file in HDFS. The mapping must convert the hierarchical data to relational data and write it to a relational target.

You can use the extracted data for business analytics.

The following figure shows the example mapping:

![HDFS Data Extraction Mapping Example](image)

You can use the following objects in the HDFS mapping:

**HDFS Input**

The input, Read_Complex_File, is a compressed XML file stored in HDFS.

**Data Processor Transformation**

The Data Processor transformation, Data_Processor_XML_to_Relational, parses the XML file and provides a relational output.

**Relational Output**

The output, Write_Relational_Data_Object, is a table in an Oracle database.
When you run the mapping, the Data Integration Service reads the file in a binary stream and passes it to the Data Processor transformation. The Data Processor transformation parses the specified file and provides a relational output. The output is written to the relational target.

You can configure the mapping to run in a native or Hadoop run-time environment.

Complete the following tasks to configure the mapping:

1. Create an HDFS connection to read files from the Hadoop cluster.
2. Create a complex file data object read operation. Specify the following parameters:
   - The file as the resource in the data object.
   - The file compression format.
   - The HDFS file location.
3. Optionally, you can specify the input format that the Mapper uses to read the file.
4. Drag and drop the complex file data object read operation into a mapping.
5. Create a Data Processor transformation. Configure the following properties in the Data Processor transformation:
   - An input port set to buffer input and binary data type.
   - Relational output ports depending on the number of columns you want in the relational output. Specify the port size for the ports. Use an XML schema reference that describes the XML hierarchy. Specify the normalized output that you want. For example, you can specify PurchaseOrderNumber_Key as a generated key that relates the Purchase Orders output group to a Customer Details group.
   - Create a Streamer object and specify Streamer as a startup component.
6. Create a relational connection to an Oracle database.
7. Import a relational data object.
8. Create a write transformation for the relational data object and add it to the mapping.

Hive Mappings

Based on the mapping environment, you can read data from or write data to Hive.

In a native environment, you can read data from Hive. To read data from Hive, complete the following steps:

1. Create a Hive connection.
2. Configure the Hive connection mode to access Hive as a source or target.
3. Use the Hive connection to create a data object to read from Hive.
4. Add the data object to a mapping and configure the mapping to run in the native environment.

You can write to Hive in a Hadoop environment. To write data to Hive, complete the following steps:

1. Create a Hive connection.
2. Configure the Hive connection mode to access Hive as a source or target.
3. Use the Hive connection to create a data object to write to Hive.
4. Add the data object to a mapping and configure the mapping to run in the Hadoop environment.
You can define the following types of objects in a Hive mapping:

- A read data object to read data from Hive
- Transformations
- A target or an SQL data service. You can write to Hive if you run the mapping in a Hadoop cluster.

Validate and run the mapping. You can deploy the mapping and run it or add the mapping to a Mapping task in a workflow.

**Hive Mapping Example**

Your organization, HypoMarket Corporation, needs to analyze customer data. Create a mapping that reads all the customer records. Create an SQL data service to make a virtual database available for end users to query.

You can use the following objects in a Hive mapping:

**Hive input**

The input file is a Hive table that contains the customer names and contact details.

Create a relational data object. Configure the Hive connection and specify the table that contains the customer data as a resource for the data object. Drag the data object into a mapping as a read data object.

**SQL Data Service output**

Create an SQL data service in the Developer tool. To make it available to end users, include it in an application, and deploy the application to a Data Integration Service. When the application is running, connect to the SQL data service from a third-party client tool by supplying a connect string.

You can run SQL queries through the client tool to access the customer data.

**Social Media Mappings**

Create mappings to read social media data from sources such as Facebook and LinkedIn.

You can extract social media data and load them to a target in the native environment only. You can choose to parse this data or use the data for data mining and analysis.

To process or analyze the data in Hadoop, you must first move the data to a relational or flat file target and then run the mapping in the Hadoop cluster.

You can use the following Informatica adapters in the Developer tool:

- PowerExchange for DataSift
- PowerExchange for Facebook
- PowerExchange for LinkedIn
- PowerExchange for Twitter
- PowerExchange for Web Content-Kapow Katalyst

Review the respective PowerExchange adapter documentation for more information.
Twitter Mapping Example

Your organization, Hypomarket Corporation, needs to review all the tweets that mention your product HypoBasket with a positive attitude since the time you released the product in February 2012.

Create a mapping that identifies tweets that contain the word HypoBasket and writes those records to a table.

You can use the following objects in a Twitter mapping:

**Twitter input**

The mapping source is a Twitter data object that contains the resource Search.

Create a physical data object and add the data object to the mapping. Add the Search resource to the physical data object. Modify the query parameter with the following query:

```
QUERY={HypoBasket} \& since:2012-02-01
```

**Sorter transformation**

Optionally, sort the data based on the timestamp.

Add a Sorter transformation to the mapping. Specify the timestamp as the sort key with direction as ascending.

**Mapping output**

Add a relational data object to the mapping as a target.

After you run the mapping, Data Integration Service writes the extracted tweets to the target table. You can use text analytics and sentiment analysis tools to analyze the tweets.
Profiles Overview

You can create and run column profiles, enterprise discovery profiles, and scorecards in the native run-time environment or Hadoop run-time environment.

When you create or edit a profile or scorecard, you can choose the run-time environment. After you choose the run-time environment, the Developer tool or the Analyst tool sets the run-time environment in the profile definition. To process the profiles quickly, you can choose the Hadoop run-time environment.

Native Environment

In Informatica Developer, you can run single object profiles, multiple object profiles, and enterprise discovery profiles in the native environment. In Informatica Analyst, you can run column profiles, enterprise discovery profiles, and scorecards in the native environment.

When you run a profile in the native run-time environment, the Analyst tool or Developer tool submits the profile jobs to the Profiling Service Module. The Profiling Service Module then breaks down the profile jobs into a set of mappings. The Data Integration Service runs these mappings on the same machine where the Data Integration Service runs and writes the profile results to the profiling warehouse. By default, all profiles run in the native run-time environment.
You can use native sources to create and run profiles in the native environment. A native data source is a non-Hadoop source, such as a flat file, relational source, or mainframe source. You can also run a profile on a mapping specification or a logical data source with a Hive or HDFS data source in the native environment.

Hadoop Environment

You can run profiles and scorecards in the Hadoop environment on the Hive engine or Blaze engine.

The Hive engine is a batch processing engine that uses Hadoop technology such as MapReduce or Tez. Informatica Blaze engine is an Informatica proprietary engine for distributed processing on Hadoop.

When you run a profile in the Hadoop environment, the Analyst tool or Developer tool submits the profile jobs to the Profiling Service Module. The Profiling Service Module then breaks down the profile jobs into a set of mappings. The Data Integration Service pushes the mappings to the Hadoop environment through a Hive connection or Hadoop connection. The Hive engine or Blaze engine processes the mappings and the Data Integration Service writes the profile results to the profiling warehouse.

In the Developer tool, you can run single object profiles and multiple object profiles on the Hive engine and Blaze engine. You can run enterprise discovery profiles on the Blaze engine.

In the Analyst tool, you can run column profiles on the Hive engine and Blaze engine. You can run enterprise discovery profiles and scorecards on the Blaze engine.

You can use native or Hadoop data sources to create and run profiles in the Hadoop environment. A Hadoop data source is a Hive, HDFS, or Sqoop source. A Sqoop data source can be Aurora, Greenplum, IBM DB2, IBM DB2 for z/OS, Microsoft SQL Server, Netezza, Oracle, or Teradata. You can choose to run a native source in the Hadoop run-time environment when the volume of data in the data source is huge or to process the data faster. You can also run a profile on a mapping specification or a logical data source with a Hive or HDFS data source in the Hadoop environment.

Column Profiles for Sqoop Data Sources

You can run a column profile on data objects that use Sqoop. You must select the Hive run-time environment to run column profiles.

To run a column profile on a relational data object that uses Sqoop, you must set the Sqoop argument m to 1. Use the following syntax:

```
-m 1
```

To run a column profile on a logical data object or customized data object that uses Sqoop, you do not need to set the Sqoop argument m to 1. You can configure the num-mappers argument to achieve parallelism and improve performance. If you configure the num-mappers argument, you must also configure the split-by argument to specify the column based on which the Sqoop program must split the work units. If you do not configure the split-by argument, the value of the num-mappers argument defaults to 1.
Creating a Single Data Object Profile in Informatica Developer

You can create a single data object profile for one or more columns in a data object and store the profile object in the Model repository.

1. In the Object Explorer view, select the data object you want to profile.
2. Click File > New > Profile to open the profile wizard.
3. Select Profile and click Next.
4. Enter a name for the profile and verify the project location. If required, browse to a new location.
5. Optionally, enter a text description of the profile.
6. Verify that the name of the data object you selected appears in the Data Objects section.
7. Click Next.
8. Configure the profile operations that you want to perform. You can configure the following operations:
   • Column profiling
   • Primary key discovery
   • Functional dependency discovery
   • Data domain discovery
   Note: To enable a profile operation, select Enabled as part of the "Run Profile" action for that operation. Column profiling is enabled by default.
9. Review the options for your profile.
   You can edit the column selection for all profile types. Review the filter and sampling options for column profiles. You can review the inference options for primary key, functional dependency, and data domain discovery. You can also review data domain selection for data domain discovery.
10. Review the drill-down options, and edit them if necessary. By default, the Enable Row Drilldown option is selected. You can edit drill-down options for column profiles. The options also determine whether drill-down operations read from the data source or from staged data, and whether the profile stores result data from previous profile runs.
11. In the Run Settings section, configure the validation environments and run-time environment. You can choose Native, Hive, or Hadoop as the validation environment. You can choose the Native, Hive, or Hadoop as the run-time environment. When you choose Hive, select a Hive connection. When you choose Hadoop, select a Blaze connection.
12. Click Finish.

Creating an Enterprise Discovery Profile in Informatica Developer

You can create a profile on multiple data sources under multiple connections. The Developer tool creates individual profile tasks for each source.

1. In the Object Explorer view, select multiple data objects you want to run a profile on.
2. Click File > New > Profile to open the profile wizard.
3. Select **Enterprise Discovery Profile** and click **Next**.

4. Enter a name for the profile and verify the project location. If required, browse to a new location.

5. Verify that the name of the data objects you selected appears within the **Data Objects** section. Click **Choose** to select more data objects, if required.

6. Click **Next**.

The **Add Resources to Profile Definition** pane appears. You can select multiple, external relational connections and data sources from this pane.

7. Click **Choose** to open the **Select Resources** dialog box.

The **Resources** pane lists all the internal and external connections and data objects under the Informatica domain.

8. Click **OK** to close the dialog box.

9. Click **Next**.

10. Configure the profile types that you want to run. You can configure the following profile types:

    - Data domain discovery
    - Column profile
    - Primary key profile
    - Foreign key profile

**Note:** Select **Enabled as part of "Run Enterprise Discovery Profile" action** for the profile types that you want to run as part of the enterprise discovery profile. Column profiling is enabled by default.

11. Review the options for the profile.

    You can edit the sampling options for column profiles. You can also edit the inference options for data domain, primary key, and foreign key profiles.

12. Select **Create profiles**.

    The Developer tool creates profiles for each individual data source.

13. Select **Run enterprise discovery profile on finish** to run the profile when you complete the profile configuration. If you enabled all the profiling operations, the Developer tool runs column, data domain, and primary key profiles on all selected data sources. Then, the Developer tool runs a foreign key profile across all the data sources.

14. Click **Finish**.

After you run an enterprise discovery profile, you need to refresh the Model Repository Service before viewing the results. This step is required as the import of metadata for external connections happens in the Model repository. You need to refresh the Model Repository Service so that the Developer tool reflects the changes to the Model repository.
Creating a Column Profile in Informatica Analyst

You can create a custom profile or default profile. When you create a custom profile, you can configure the columns, sample rows, and drill-down options. When you create a default profile, the column profile and data domain discovery runs on the entire data set with all the data domains.

1. In the **Discovery** workspace, click **Profile**, or select **New > Profile** from the header area.
   
   **Note**: You can right-click on the data object in the **Library** workspace and create a profile. In this profile, the profile name, location name, and data object are extracted from the data object properties. You can create a default profile or customize the settings to create a custom profile.

   The New Profile wizard appears.

2. The **Single source** option is selected by default. Click **Next**.

3. In the **Specify General Properties** screen, enter a name and an optional description for the profile. In the Location field, select the project or folder where you want to create the profile. Click **Next**.

4. In the **Select Source** screen, click **Choose** to select a data object, or click **New** to import a data object. Click **Next**.
   
   - In the **Choose Data Object** dialog box, select a data object. Click **OK**. The Properties pane displays the properties of the selected data object. The Data Preview pane displays the columns in the data object.
   
   - In the **New Data Object** dialog box, you can choose a connection, schema, table, or view to create a profile on, select a location, and create a folder to import the data object. Click **OK**.

5. In the **Select Source** screen, select the columns that you want to run a profile on. Optionally, select **Name** to select all the columns. Click **Next**.

   All the columns are selected by default. The Analyst tool lists column properties, such as the name, data type, precision, scale, nullable, and participates in the primary key for each column.

6. In the **Specify Settings** screen, choose to run a column profile, data domain discovery, or a column profile with data domain discovery. By default, column profile option is selected.

   - Choose **Run column profile** to run a column profile.
   
   - Choose **Run data domain discovery** to perform data domain discovery. In the **Data domain** pane, select the data domains that you want to discover, select a conformance criteria, and select the columns for data domain discovery in the **Edit columns selection for data domain discovery** dialog box.
   
   - Choose **Run column profile** and **Run data domain discovery** to run the column profile with data domain discovery. Select the data domain options in the **Data domain** pane.

   **Note**: By default, the columns that you select is for column profile and data domain discovery. Click **Edit** to select or deselect columns for data domain discovery.

   - Choose Data, Columns, or Data and Columns to run data domain discovery on.

   - Choose a sampling option. You can choose **All rows (complete analysis)**, **Sample first**, **Random sample**, or **Random sample (auto)** as a sampling option in the **Run profile on** pane. This option applies to column profile and data domain discovery.

   - Choose a drilldown option. You can choose **Live** or **Staged** drilldown option, or you can choose **Off** to disable drilldown in the **Drilldown** pane. Optionally, click **Select Columns** to select columns to drill down on. You can choose to omit data type and data domain inference for columns with an approved data type or data domain.

   - Choose **Native**, **Hive**, or **Hadoop** as the run-time environment. If you choose Hive, click **Choose** to select a Hive connection in the **Select a Hive Connection** dialog box. If you choose Hadoop, click **Choose** to select a Blaze connection in the **Select a Hadoop Connection** dialog box.
7. Click Next.
The Specify Rules and Filters screen opens.

8. In the Specify Rules and Filters screen, you can perform the following tasks:
   • Create, edit, or delete a rule. You can apply existing rules to the profile.
   • Create, edit, or delete a filter.
     Note: When you create a scorecard on this profile, you can reuse the filters that you create for the profile.

9. Click Save and Finish to create the profile, or click Save and Run to create and run the profile.

Creating an Enterprise Discovery Profile in Informatica Analyst

You can run column profile and data domain discovery as part of enterprise discovery in Informatica Analyst.

1. In the Discovery workspace, select New > Profile.
The New Profile wizard appears.

2. Select Enterprise Discovery. Click Next.
The Specify General Properties tab appears.

3. In the Specify General Properties tab, enter a name for the enterprise discovery profile and an optional description. In the Location field, select the project or folder where you want to create the profile. Click Next.
The Select Data Objects tab appears.

4. In the Select Data Objects tab, click Choose.
The Choose Data objects dialog box appears.

5. In the Choose Data objects dialog box, choose one or more data objects to add to the profile. Click Save.
The data objects appear in the Data Objects pane.

6. Click Next.
The Select Resources tab appears.

7. In the Select Resources tab, click Choose to open the Select Resources tab.
You can import data from multiple relational data sources.

8. In the Select Resources tab, select the connections, schemas, tables, and views that you want to include in the profile. Click Save.
The left pane in the dialog box lists all the internal and external connections, schemas, tables, and views under the Informatica domain.
The resources appear in the Resource pane.

9. Click Next.
The Specify Settings tab appears.

10. In the Specify Settings tab, you can configure the column profile options and data domain discovery options. Click Save and Finish to save the enterprise discovery profile, or click Save and Run to run the profile.
You can perform the following tasks in the Specify Settings tab.

- Enable data domain discovery. Click Choose to select data domains that you want to discover from the Choose Data Domains dialog box. The selected data domains appear in the Data Domains for Data Domain Discovery pane.
- Run data domain on data, column name, or on both data and column name.
- Select all the rows in the data source, or choose a maximum number of rows to run domain discovery on.
- Choose a minimum conformance percentage or specify the minimum number of conforming rows for data domain discovery.
- Enable column profile settings and select all rows or first few rows in the data source for the column profile. You can exclude data type inference for columns with approved data types in the column profile.
- Choose Native or Hadoop as the run-time environment.

You can view the enterprise discovery results under the Summary and Profiles tabs.

## Creating a Scorecard in Informatica Analyst

Create a scorecard and add columns from a profile to the scorecard. You must run a profile before you add columns to the scorecard.

1. In the Library workspace, select the project or folder that contains the profile.
2. Click the profile to open the profile. The profile results appear in the summary view in the Discovery workspace.
3. Click Actions > Add to scorecard.
   The Add to Scorecard wizard appears.
4. In the Add to Scorecard screen, you can choose to create a new scorecard, or edit an existing scorecard to add the columns to a predefined scorecard. The New Scorecard option is selected by default. Click Next.
5. In the Step 2 of 8 screen, enter a name for the scorecard. Optionally, you can enter a description for the scorecard. Select the project and folder where you want to save the scorecard. Click Next.
   By default, the scorecard wizard selects the columns and rules defined in the profile. You cannot add columns that are not included in the profile.
6. In the Step 3 of 8 screen, select the columns and rules that you want to add to the scorecard as metrics. Optionally, click the check box in the left column header to select all columns. Optionally, select Column Name to sort column names. Click Next.
7. In the Step 4 of 8 screen, you can add a filter to the metric.
   You can apply the filter that you created for the profile to the metrics, or create a new filter. Select a metric in the Metric Filters pane, and click the Manage Filters icon to open the Edit Filter: column name dialog box. In the Edit Filter: column name dialog box, you can choose to perform one of the following tasks:
   - You can choose a filter that you created for the profile. Click Next.
   - Select an existing filter. Click edit icon to edit the filter in the Edit Filter dialog box. Click Next.
   - Click the plus (+) icon to create filters in the New Filter dialog box. Click Next.
The filter appears in the **Metric Filters** pane. You can apply the same filter to all the metrics in the scorecard.

8. In the **Step 4 of 8** screen, click **Next**.

9. In the **Step 5 of 8** screen, select each metric in the **Metrics** pane and configure the valid values from the list of all values in the **Score using: Values** pane. You can perform the following tasks in the **Step 5 of 7** screen:
   - You can select multiple values in the **Available Values** pane, and click the right arrow button to move them to the **Valid Values** pane. The total number of valid values for a metric appears at the top of the **Available Values** pane.
   - In the **Metric Thresholds** pane, configure metric thresholds.
     You can set thresholds for **Good**, **Acceptable**, and **Unacceptable** scores.
   - Select each metric and configure the cost of invalid data. To assign a constant value to the cost for the metric, select **Fixed Cost**. Optionally, click **Change Cost Unit** to change the unit of cost or choose **None**. To attach a numeric column as a variable cost to the metric, select **Variable Cost**, and click **Select Column** to select a numeric column.

10. In the **Step 6 of 8** screen, you can select a metric group to which you can add the metrics, or create a new metric group. To create a new metric group, click the group icon. Click **Next**.

11. In the **Step 7 of 8** screen, specify the weights for the metrics in the group and thresholds for the group.

12. In the **Step 8 of 8** screen, select **Native** or **Hadoop** as the run-time environment to run the scorecard.

13. Click **Save** to save the scorecard, or click **Save & Run** to save and run the scorecard.

The scorecard appears in the **Scorecard** workspace.

---

**Monitoring a Profile**

You can monitor a profile in the Administrator tool.

1. In the Administrator tool, click the **Monitor** tab.
2. In the Navigator workspace, select **Jobs**.
3. Select a profiling job.
4. In the **Summary Statistics** tab, you can view the general properties of the profile, summary statistics, and detailed statistics of the profile.
5. Click the **Execution Statistics** tab to view execution statistics for the profile.

---

**Troubleshooting**

**Can I drill down on profile results if I run a profile in the Hadoop environment?**

Yes, except for profiles in which you have set the option to drill down on staged data.
I get the following error message when I run a profile in the Hadoop environment: “[LDTM_1055] The Integration Service failed to generate a Hive workflow for mapping [Profile_CUSTOMER_INFO12_14258652520457390].” How do I resolve this?

This error can result from a data source, rule transformation, or run-time environment that is not supported in the Hadoop environment. For more information about objects that are not valid in the Hadoop environment, see the Mappings in a Hadoop Environment chapter.

You can change the data source, rule, or run-time environment and run the profile again. View the profile log file for more information on the error.

I see "N/A" in the profile results for all columns after I run a profile. How do I resolve this?

Verify that the profiling results are in the profiling warehouse. If you do not see the profile results, verify that the database path is accurate in the HadoopEnv.properties file. You can also verify the database path from the Hadoop job tracker on the Monitoring tab of the Administrator tool.

After I run a profile on a Hive source, I do not see the results. When I verify the Hadoop job tracker, I see the following error when I open the profile job: "XML Parsing Error: no element found." What does this mean?

The Hive data source does not have any record and is empty. The data source must have a minimum of one row of data for successful profile run.

After I run a profile on a Hive source, I cannot view some of the column patterns. Why?

When you import a Hive source, the Developer tool sets the precision for string columns to 4000. The Developer tool cannot derive the pattern for a string column with a precision greater than 255. To resolve this issue, set the precision of these string columns in the data source to 255 and run the profile again.

When I run a profile on large Hadoop sources, the profile job fails and I get an "execution failed" error. What can be the possible cause?

One of the causes can be a connection issue. Perform the following steps to identify and resolve the connection issue:

1. Open the Hadoop job tracker.
2. Identify the profile job and open it to view the MapReduce jobs.
3. Click the hyperlink for the failed job to view the error message. If the error message contains the text "java.net.ConnectException: Connection refused", the problem occurred because of an issue with the Hadoop cluster. Contact your network administrator to resolve the issue.
CHAPTER 7

Native Environment Optimization

This chapter includes the following topics:

- Native Environment Optimization Overview, 98
- Processing Big Data on a Grid, 98
- Processing Big Data on Partitions, 99
- High Availability, 100

Native Environment Optimization Overview

You can optimize the native environment to increase performance. To increase performance, you can configure the Data Integration Service to run on a grid and to use multiple partitions to process data. You can also enable high availability to ensure that the domain can continue running despite temporary network, hardware, or service failures.

You can run profiles, sessions, and workflows on a grid to increase the processing bandwidth. A grid is an alias assigned to a group of nodes that run profiles, sessions, and workflows. When you enable grid, the Data Integration Service runs a service process on each available node of the grid to increase performance and scalability.

You can also run mapping with partitioning to increase performance. When you run a partitioned session or a partitioned mapping, the Data Integration Service performs the extract, transformation, and load for each partition in parallel.

You can configure high availability for the domain. High availability eliminates a single point of failure in a domain and provides minimal service interruption in the event of failure.

Processing Big Data on a Grid

You can run an Integration Service on a grid to increase the processing bandwidth. When you enable grid, the Integration Service runs a service process on each available node of the grid to increase performance and scalability.

Big data may require additional bandwidth to process large amounts of data. For example, when you run a Model repository profile on an extremely large data set, the Data Integration Service grid splits the profile into multiple mappings and runs the mappings simultaneously on different nodes in the grid.
Data Integration Service Grid

You can run Model repository mappings and profiles on a Data Integration Service grid.

When you run mappings on a grid, the Data Integration Service distributes the mappings to multiple DTM processes on nodes in the grid. When you run a profile on a grid, the Data Integration Service splits the profile into multiple mappings and distributes the mappings to multiple DTM processes on nodes in the grid.

For more information about the Data Integration Service grid, see the Informatica Administrator Guide.

Grid Optimization

You can optimize the grid to increase performance and scalability of the Data Integration Service.

To optimize the grid, complete the following task:

Add nodes to the grid.

Add nodes to the grid to increase processing bandwidth of the Data Integration Service.

Processing Big Data on Partitions

You can run a Model repository mapping with partitioning to increase performance. When you run a mapping configured with partitioning, the Data Integration Service performs the extract, transformation, and load for each partition in parallel.

Mappings that process large data sets can take a long time to process and can cause low data throughput. When you configure partitioning, the Data Integration Service uses additional threads to process the session or mapping which can increase performance.

Partitioned Model Repository Mappings

You can enable the Data Integration Service to use multiple partitions to process Model repository mappings.

If the nodes where mappings run have multiple CPUs, you can enable the Data Integration Service to maximize parallelism when it runs mappings. When you maximize parallelism, the Data Integration Service dynamically divides the underlying data into partitions and processes all of the partitions concurrently.

Optionally, developers can set a maximum parallelism value for a mapping in the Developer tool. By default, the maximum parallelism for each mapping is set to Auto. Each mapping uses the maximum parallelism value defined for the Data Integration Service. Developers can change the maximum parallelism value in the mapping run-time properties to define a maximum value for a particular mapping. When maximum parallelism is set to different integer values for the Data Integration Service and the mapping, the Data Integration Service uses the minimum value.

For more information, see the Informatica Application Services Guide and the Informatica Developer Mapping Guide.
Partition Optimization

You can optimize the partitioning of Model repository mappings to increase performance. You can add more partitions, select the best performing partition types, use more CPUs, and optimize the source or target database for partitioning.

To optimize partitioning, perform the following tasks:

**Increase the number of partitions.**

When you configure Model repository mappings, you increase the number of partitions when you increase the maximum parallelism value for the Data Integration Service or the mapping.

Increase the number of partitions to enable the Data Integration Service to create multiple connections to sources and process partitions of source data concurrently. Increasing the number of partitions increases the number of threads, which also increases the load on the Data Integration Service nodes. If the Data Integration Service node or nodes contain ample CPU bandwidth, processing rows of data concurrently can increase performance.

**Note:** If you use a single-node Data Integration Service and the Data Integration Service uses a large number of partitions in a session or mapping that processes large amounts of data, you can overload the system.

**Use multiple CPUs.**

If you have a symmetric multi-processing (SMP) platform, you can use multiple CPUs to concurrently process partitions of data.

**Optimize the source database for partitioning.**

You can optimize the source database for partitioning. For example, you can tune the database, enable parallel queries, separate data into different tablespaces, and group sorted data.

**Optimize the target database for partitioning.**

You can optimize the target database for partitioning. For example, you can enable parallel inserts into the database, separate data into different tablespaces, and increase the maximum number of sessions allowed to the database.

High Availability

High availability eliminates a single point of failure in an Informatica domain and provides minimal service interruption in the event of failure. When you configure high availability for a domain, the domain can continue running despite temporary network, hardware, or service failures. You can configure high availability for the domain, application services, and application clients.

The following high availability components make services highly available in an Informatica domain:

- **Resilience.** An Informatica domain can tolerate temporary connection failures until either the resilience timeout expires or the failure is fixed.
- **Restart and failover.** A process can restart on the same node or on a backup node after the process becomes unavailable.
- **Recovery.** Operations can complete after a service is interrupted. After a service process restarts or fails over, it restores the service state and recovers operations.

When you plan a highly available Informatica environment, consider the differences between internal Informatica components and systems that are external to Informatica. Internal components include the
Service Manager, application services, and command line programs. External systems include the network, hardware, database management systems, FTP servers, message queues, and shared storage.

High availability features for the Informatica environment are available based on your license.
Data Type Reference

This appendix includes the following topics:

- Data Type Reference Overview, 102
- Transformation Data Type Support in a Hadoop Environment, 102
- Hive Data Types and Transformation Data Types, 103
- Hive Complex Data Types, 104
- Sqoop Data Types, 104

Data Type Reference Overview

Informatica Developer uses the following data types in Hive mappings:

- Hive native data types. Hive data types appear in the physical data object column properties.
- Transformation data types. Set of data types that appear in the transformations. They are internal data types based on ANSI SQL-92 generic data types, which the Data Integration Service uses to move data across platforms. Transformation data types appear in all transformations in a mapping.

When the Data Integration Service reads source data, it converts the native data types to the comparable transformation data types before transforming the data. When the Data Integration Service writes to a target, it converts the transformation data types to the comparable native data types.

Transformation Data Type Support in a Hadoop Environment

The following table shows the Informatica transformation data type support in a Hadoop environment:

<table>
<thead>
<tr>
<th>Transformation Data Type</th>
<th>Support</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bigint</td>
<td>Supported</td>
</tr>
<tr>
<td>Binary</td>
<td>Supported</td>
</tr>
<tr>
<td>Date/Time</td>
<td>Supported</td>
</tr>
</tbody>
</table>
### Hive Data Types and Transformation Data Types

The following table lists the Hive data types that Data Integration Service supports and the corresponding transformation data types:

<table>
<thead>
<tr>
<th>Hive Data Type</th>
<th>Transformation Data Type</th>
<th>Range and Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Binary</td>
<td>Binary</td>
<td>1 to 104,857,600 bytes. You can read and write data of Binary data type in a Hadoop environment. You can use the user-defined functions to transform the binary data type.</td>
</tr>
<tr>
<td>Tiny Int</td>
<td>Integer</td>
<td>-32,768 to 32,767</td>
</tr>
<tr>
<td>Integer</td>
<td>Integer</td>
<td>-2,147,483,648 to 2,147,483,647 Precision 10, scale 0</td>
</tr>
<tr>
<td>Bigint</td>
<td>Bigint</td>
<td>-9,223,372,036,854,775,808 to 9,223,372,036,854,775,807 Precision 19, scale 0</td>
</tr>
<tr>
<td>Decimal</td>
<td>Decimal</td>
<td>If a mapping is not enabled for high precision, the Data Integration Service converts all decimal values to double values. If a mapping is enabled for high precision, the Data Integration Service converts decimal values with precision greater than 38 digits to double values.</td>
</tr>
<tr>
<td>Double</td>
<td>Double</td>
<td>Precision 15</td>
</tr>
<tr>
<td>Float</td>
<td>Double</td>
<td>Precision 15</td>
</tr>
<tr>
<td>String</td>
<td>String</td>
<td>1 to 104,857,600 characters</td>
</tr>
<tr>
<td>Boolean</td>
<td>Integer</td>
<td>1 or 0 The default transformation type for boolean is integer. You can also set this to string data type with values of True and False.</td>
</tr>
<tr>
<td>Hive Data Type</td>
<td>Transformation Data Type</td>
<td>Range and Description</td>
</tr>
<tr>
<td>----------------</td>
<td>--------------------------</td>
<td>-----------------------</td>
</tr>
<tr>
<td>Arrays</td>
<td>String</td>
<td>1 to 104,857,600 characters</td>
</tr>
<tr>
<td>Struct</td>
<td>String</td>
<td>1 to 104,857,600 characters</td>
</tr>
<tr>
<td>Maps</td>
<td>String</td>
<td>1 to 104,857,600 characters</td>
</tr>
<tr>
<td>Timestamp</td>
<td>datetime</td>
<td>The time stamp format is YYYY-MM-DD HH:MM:SS.ffffffff. Precision 29, scale 9.</td>
</tr>
<tr>
<td>Date</td>
<td>datetime</td>
<td>0000-0101 to 999912-31. Hive date format is YYYY-MM-DD. Precision 10, scale 0.</td>
</tr>
<tr>
<td>Char</td>
<td>String</td>
<td>1 to 255 characters</td>
</tr>
<tr>
<td>Varchar</td>
<td>String</td>
<td>1 to 65355 characters</td>
</tr>
</tbody>
</table>

**Hive Complex Data Types**

Hive complex data types such as arrays, maps, and structs are a composite of primitive or complex data types. Informatica Developer represents complex data types with the string data type and uses delimiters to separate the elements of the complex data type.

**Note:** Hive complex data types in a Hive source or Hive target are not supported when you run mappings in a Hadoop cluster.

The following table describes the transformation types and delimiters that are used to represent the complex data types:

<table>
<thead>
<tr>
<th>Complex Data Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Array</td>
<td>The elements in the array are of string data type. The elements in the array are delimited by commas. For example, an array of fruits is represented as [apple,banana,orange].</td>
</tr>
<tr>
<td>Map</td>
<td>Maps contain key-value pairs and are represented as pairs of strings and integers delimited by the = character. String and integer pairs are delimited by commas. For example, a map of fruits is represented as [1=apple,2=banana,3=orange].</td>
</tr>
<tr>
<td>Struct</td>
<td>Structs are represented as pairs of strings and integers delimited by the : character. String and integer pairs are delimited by commas. For example, a struct of fruits is represented as [1,apple].</td>
</tr>
</tbody>
</table>

**Sqoop Data Types**

When you use Sqoop, some variations apply in the processing.
The following table summarizes the data types that Informatica supports when you use Sqoop:

<table>
<thead>
<tr>
<th>Data Type</th>
<th>Aurora</th>
<th>IBM DB2</th>
<th>IBM DB2 for z/OS</th>
<th>Greenplum</th>
<th>Microsoft SQL Server</th>
<th>Netezza</th>
<th>Oracle</th>
<th>Teradata</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bigint</td>
<td>n/a</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
<td>Yes</td>
<td>n/a</td>
<td>Yes *</td>
<td>n/a</td>
</tr>
<tr>
<td>Bigserial</td>
<td>n/a</td>
<td>n/a</td>
<td>n/a</td>
<td>Yes</td>
<td>n/a</td>
<td>n/a</td>
<td>n/a</td>
<td>n/a</td>
</tr>
<tr>

</table>

n/a indicates that the data type is not applicable to the database.

* The data type is supported only for import.

** If the Sqoop program uses OraOop, the data type is supported only for import.

*** Microsoft SQL Server supports the INT data type.
Function Support in a Hadoop Environment

Some Informatica transformation language functions that are valid in the native environment might be supported with restrictions or unsupported in a Hadoop environment.

The following table lists functions and levels of support for functions on different engines in a Hadoop environment:

<table>
<thead>

</tbody>
</table>

*Functions not listed in this table are supported on all engines without restrictions.*
APPENDIX C

Parameter Reference

This appendix includes the following topics:

- Parameters Overview, 110
- Parameter Usage, 111

Parameters Overview

A mapping parameter represents a constant value that you can change between mapping runs. Use parameters to change the values of connections, file directories, expression components, port lists, port links, and task properties. You can use system parameters or user-defined parameters.

System parameters are built-in parameters for a Data Integration Service. System parameters define the directories where the Data Integration Service stores log files, cache files, reject files, source files, target files, and temporary files. An administrator defines the system parameter default values for a Data Integration Service in the Administrator tool.

User-defined parameters are parameters that you define in transformations, mappings, or workflows.

You can override parameter values using a parameter set or a parameter file. A parameter set is a repository object that contains mapping parameter values. A parameter file is an XML file that contains parameter values. When you run the mapping with a parameter set or a parameter file, the Data Integration Service uses the parameter values defined in the parameter set or parameter file instead of the default parameter values you configured in the transformation, mapping, or workflow.

You can use the following parameters to represent additional properties in the Hadoop environment:

- **Parameters for sources and targets**
  - You can use parameters to represent additional properties for the following big data sources and targets:
    - Complex file
    - Flat file
    - HBase
    - HDFS
    - Hive

- **Parameters for the Hadoop connection and run-time environment**
  - You can set the Hive version, run-time environment, and Hadoop connection with a parameter.

For more information about mapping parameters, see the *Informatica Developer Mapping Guide*. 
Parameter Usage

Use parameters for big data sources or target properties, connection properties, and run-time environment properties.

Big Data Sources and Targets

Hive sources
You can configure the following parameters for Hive Read transformation properties:

- Connection. Configure this parameter on the **Run-time** tab.
- Owner. Configure this parameter on the **Run-time** tab.
- Resource. Configure this parameter on the **Run-time** tab.
- Joiner queries. Configure this parameter on the **Query** tab.
- Filter queries. Configure this parameter on the **Query** tab.
- PreSQL commands. Configure this parameter on the **Advanced** tab.
- PostSQL commands. Configure this parameter on the **Advanced** tab.
- Constraints. Configure this parameter on the **Advanced** tab.

HBase sources and targets
You can configure the following parameters for HBase Read and Write transformation properties:

- Connection. Configure this parameter on the **Overview** tab.
- Date Time Format for the Read or Write data object. Configure this parameter on the **Advanced** tab.

Complex file sources and targets
You can configure the following parameters for complex file Read and Write transformation properties:

- Connection. Configure this parameter on the **Overview** tab.
- Data object read operation. Configure the following parameters on the **Advanced** tab:
  - File Path
  - File Format.
  - Input Format
  - Compression Format
  - Custom Compression Codec properties
- Data object write operation. Configure the following parameters on the **Advanced** tab:
  - File Name
  - File Format
  - Output Format
  - Output Key Class
  - Output Value Class
  - Compression Format
  - Custom Compression Codec
  - Sequence File Compression Type
Flat file on HDFS sources and targets

You can configure the following parameters for a flat file on HDFS Read and Write transformation properties:

- Data object read operation. Configure the following parameters on the Run-time tab:
  - Source File Name
  - Source File Directory
- Data object write operation. Configure the following parameters on the Run-time tab:
  - Output File Directory
  - Output File Name

Hadoop connection and run-time environment

You can configure the following mapping parameters on the Run-time tab for a mapping in the Hadoop environment:

- Hive version.
- Run-time environment.
- Hadoop connection.
